

# The FRANZ LISP Manual

by

*John K. Foderaro*

*Keith L. Sklower*

*Kevin Layer*

June 1983

A document in  
four movements

*Overture*

*A chorus of students under the direction of Richard Fateman have contributed to building FRANZ LISP from a mere melody into a full symphony . The major contributors to the initial system were Mike Curry, John Breedlove and Jeff Levinsky. Bill Rowan added the garbage collector and array package. Tom London worked on an early compiler and helped in overall system design. Keith Sklower has contributed much to FRANZ LISP, adding the bignum package and rewriting most of the code to increase its efficiency and clarity. Kipp Hickman and Charles Koester added hunks. Mitch Marcus added \*rset, evalhook and evalframe. Don Cohen and others at Carnegie-Mellon made some improvements to evalframe and provided various features modelled after UCI/CMU PDP-10 Lisp and Interlisp environments (editor, debugger, top-level). John Foderaro wrote the compiler, added a few functions, and wrote much of this manual. Of course, other authors have contributed specific chapters as indicated. Kevin Layer modified the compiler to produce code for the Motorola 68000, and helped make FRANZ LISP pass "Lint".*

*This manual may be supplemented or supplanted by local chapters representing alterations, additions and deletions. We at U.C. Berkeley are pleased to learn of generally useful system features, bug fixes, or useful program packages, and we will attempt to redistribute such contributions.*

## Score

### First Movement (*allegro non troppo*)

1. FRANZ LISP  
*Introduction to FRANZ LISP, details of data types, and description of notation*
2. Data Structure Access  
*Functions for the creation, destruction and manipulation of lisp data objects.*
3. Arithmetic Functions  
*Functions to perform arithmetic operations.*
4. Special Functions  
*Functions for altering flow of control. Functions for mapping other functions over lists.*
5. I/O Functions  
*Functions for reading and writing from ports. Functions for the modification of the reader's syntax.*
6. System Functions  
*Functions for storage management, debugging, and for the reading and setting of global Lisp status variables. Functions for doing UNIX-specific tasks such as process control.*

### Second Movement (*Largo*)

7. The Reader  
*A description of the syntax codes used by the reader. An explanation of character macros.*
8. Functions, Fclosures, and Macros  
*A description of various types of functional objects. An example of the use of foreign functions.*
9. Arrays and Vectors  
*A detailed description of the parts of an array and of Maclisp compatible arrays.*
10. Exception Handling  
*A description of the error handling sequence and of autoloading.*

### **Third Movement (Scherzo)**

11. The Joseph Lister Trace Package  
*A description of a very useful debugging aid.*
12. Liszt, the lisp compiler  
*A description of the operation of the compiler and hints for making functions compilable.*
13. CMU Top Level and File Package  
*A description of a top level with a history mechanism and a package which helps you keep track of files of lisp functions.*
- 14 Stepper  
*A description of a program which permits you to put breakpoints in lisp code and to single step it. A description of the evalhook and funcallhook mechanism.*
- 15 Fixit  
*A program which permits you to examine and modify evaluation stack in order to fix bugs on the fly.*
- 16 Lisp Editor  
*A structure editor for interactive modification of lisp code.*

### **Final Movement (allegro)**

- Appendix A - Function Index
- Appendix B - List of Special Symbols
- Appendix C - Short Subjects
  - Garbage collector, Debugging, Default Top Level*

## CHAPTER 1

### FRANZ LISP

**1.1.** FRANZ LISP<sup>†</sup> was created as a tool to further research in symbolic and algebraic manipulation, artificial intelligence, and programming languages at the University of California at Berkeley. Its roots are in a PDP-11 Lisp system which originally came from Harvard. As it grew it adopted features of Maclisp and Lisp Machine Lisp. Substantial compatibility with other Lisp dialects (Interlisp, UCILisp, CMULisp) is achieved by means of support packages and compiler switches. The heart of FRANZ LISP is written almost entirely in the programming language C. Of course, it has been greatly extended by additions written in Lisp. A small part is written in the assembly language for the current host machines, VAXen and a couple of flavors of 68000. Because FRANZ LISP is written in C, it is relatively portable and easy to comprehend.

FRANZ LISP is capable of running large lisp programs in a timesharing environment, has facilities for arrays and user defined structures, has a user controlled reader with character and word macro capabilities, and can interact directly with compiled Lisp, C, Fortran, and Pascal code.

This document is a reference manual for the FRANZ LISP system. It is not a Lisp primer or introduction to the language. Some parts will be of interest primarily to those maintaining FRANZ LISP at their computer site. There is an additional document entitled *The Franz Lisp System*, by John Foderaro, which partially describes the system implementation. FRANZ LISP, as delivered by Berkeley, includes all source code and machine readable version of this manual and system document. The system document is in a single file named "franz.n" in the "doc" subdirectory.

This document is divided into four Movements. In the first one we will attempt to describe the language of FRANZ LISP precisely and completely as it now stands (Opus 38.69, June 1983). In the second Movement we will look at the reader, function types, arrays and exception handling. In the third Movement we will look at several large support packages written to help the FRANZ LISP user, namely the trace package, compiler, fixit and stepping package. Finally the fourth movement contains an index into the other movements. In the rest of this chapter we shall examine the data types of FRANZ LISP. The conventions used in the description of the FRANZ LISP functions will be given in §1.3 -- it is very important that these conventions are understood.

**1.2. Data Types** FRANZ LISP has fourteen data types. In this section we shall look in detail at each type and if a type is divisible we shall look inside it. There is a Lisp function *type* which will return the type name of a lisp object. This is the official FRANZ LISP name for that type and we will use this name and this name only in the manual to avoid confusing the reader. The types are listed in terms of importance rather than alphabetically.

---

<sup>†</sup>It is rumored that this name has something to do with Franz Liszt [Frants List] (1811-1886) a Hungarian composer and keyboard virtuoso. These allegations have never been proven.

**1.2.0. lispval** This is the name we use to describe any Lisp object. The function *type* will never return 'lispval'.

**1.2.1. symbol** This object corresponds to a variable in most other programming languages. It may have a value or may be 'unbound'. A symbol may be *lambda bound* meaning that its current value is stored away somewhere and the symbol is given a new value for the duration of a certain context. When the Lisp processor leaves that context, the symbol's current value is thrown away and its old value is restored.

A symbol may also have a *function binding*. This function binding is static; it cannot be lambda bound. Whenever the symbol is used in the functional position of a Lisp expression the function binding of the symbol is examined (see Chapter 4 for more details on evaluation).

A symbol may also have a *property list*, another static data structure. The property list consists of a list of an even number of elements, considered to be grouped as pairs. The first element of the pair is the *indicator* the second the *value* of that indicator.

Each symbol has a print name (*pname*) which is how this symbol is accessed from input and referred to on (printed) output.

A symbol also has a hashlink used to link symbols together in the oblist -- this field is inaccessible to the lisp user.

Symbols are created by the reader and by the functions *concat*, *maknam* and their derivatives. Most symbols live on FRANZ LISP's sole *oblist*, and therefore two symbols with the same print name are usually the exact same object (they are *eq*). Symbols which are not on the oblist are said to be *uninterned*. The function *maknam* creates uninterned symbols while *concat* creates *interned* ones.

Subpart name	Get value	Set value	Type
value	eval	set setq	lispval
property list	plist get	setplist putprop defprop	list or nil
function binding	getd	putd def	array, binary, list or nil
print name	get_pname		string
hash link			

**1.2.2. list** A list cell has two parts, called the car and cdr. List cells are created by the function *cons*.

Subpart name	Get value	Set value	Type
car	car	rplaca	lispval
cdr	cdr	rplacd	lispval

**1.2.3. binary** This type acts as a function header for machine coded functions. It has two parts, a pointer to the start of the function and a symbol whose print name describes the argument *discipline*. The discipline (if *lambda*, *macro* or *nlambda*) determines whether the arguments to this function will be evaluated by the caller before this function is called. If the discipline is a string (specifically "subroutine", "function", "integer-function", "real-function", "c-function", "double-c-function", or "vector-c-function" ) then this function is a foreign subroutine or function (see §8.5 for more details on this). Although the type of the *entry* field of a binary type object is usually **string** or **other**, the object pointed to is actually a sequence of machine instructions.

Objects of type binary are created by *mfunction*, *cfasl*, and *getaddress*.

Subpart name	Get value	Set value	Type
entry	getentry		string or fixnum
discipline	getdisc	putdisc	symbol or fixnum

**1.2.4. fixnum** A fixnum is an integer constant in the range  $[-2^{31}, 2^{31}-1]$ . Small fixnums (-1024 to 1023) are stored in a special table so they needn't be allocated each time one is needed. In principle, the range for fixnums is machine dependent, although all current implementations for franz have this range.

**1.2.5. flonum** A flonum is a double precision real number. On the VAX, the range is  $[2.9 \times 10^{-37}, 1.7 \times 10^{38}]$ . There are approximately sixteen decimal digits of precision. Other machines may have other ranges.

**1.2.6. bignum** A bignum is an integer of potentially unbounded size. When integer arithmetic exceeds the limits of fixnums mentioned above, the calculation is automatically done with bignums. Should calculation with bignums give a result which can be represented as a fixnum, then the fixnum representation will be used<sup>†</sup>. This contraction is known as *integer normalization*. Many Lisp functions assume that integers are normalized. Bignums are composed of a sequence of **list** cells and a cell known as an **sdot**. The user should consider a **bignum** structure indivisible and use functions such as *haipart*, and *bignum-leftshift* to extract parts of it.

**1.2.7. string** A string is a null terminated sequence of characters. Most functions of symbols which operate on the symbol's print name will also work on strings. The default reader syntax is set so that a sequence of characters surrounded by double quotes is a string.

---

<sup>†</sup>The current algorithms for integer arithmetic operations will return (in certain cases) a result between  $[-2^{30}, 2^{31}]$  as a bignum although this could be represented as a fixnum.

**1.2.8. port** A port is a structure which the system I/O routines can reference to transfer data between the Lisp system and external media. Unlike other Lisp objects there are a very limited number of ports (20). Ports are allocated by *infile* and *outfile* and deallocated by *close* and *resetio*. The *print* function prints a port as a percent sign followed by the name of the file it is connected to (if the port was opened by *fileopen*, *infile*, or *outfile*). During initialization, FRANZ LISP binds the symbol **piport** to a port attached to the standard input stream. This port prints as *:%\$stdin*. There are ports connected to the standard output and error streams, which print as *:%\$stdout* and *:%\$stderr*. This is discussed in more detail at the beginning of Chapter 5.

**1.2.9. vector** Vectors are indexed sequences of data. They can be used to implement a notion of user-defined types via their associated property list. They make **hunks** (see below) logically unnecessary, although hunks are very efficiently garbage collected. There is a second kind of vector, called an immediate-vector, which stores binary data. The name that the function *type* returns for immediate-vectors is **vectori**. Immediate-vectors could be used to implement strings and block-flonum arrays, for example. Vectors are discussed in chapter 9. The functions *new-vector*, and *vector*, can be used to create vectors.

Subpart name	Get value	Set value	Type
datum[ <i>i</i> ]	vref	vset	lispval
property	vprop	vsetprop vputprop	lispval
size	vsize	□	fixnum

**1.2.10. array** Arrays are rather complicated types and are fully described in Chapter 9. An array consists of a block of contiguous data, a function to access that data, and auxiliary fields for use by the accessing function. Since an array's accessing function is created by the user, an array can have any form the user chooses (e.g. n-dimensional, triangular, or hash table). Arrays are created by the function *marray*.

Subpart name	Get value	Set value	Type
access function	getaccess	putaccess	binary, list or symbol
auxiliary	getaux	putaux	lispval
data	arrayref	replace set	block of contiguous lispval
length	getlength	putlength	fixnum
delta	getdelta	putdelta	fixnum

**1.2.11. value** A value cell contains a pointer to a lispval. This type is used mainly by arrays of general lisp objects. Value cells are created with the *ptr* function. A value cell containing a pointer to the symbol 'foo' is printed as '(ptr to)foo'

**1.2.12. hunk** A hunk is a vector of from 1 to 128 lispsvals. Once a hunk is created (by *hunk* or *makhunk*) it cannot grow or shrink. The access time for an element of a hunk is slower than a list cell element but faster than an array. Hunks are really only allocated in sizes which are powers of two, but can appear to the user to be any size in the 1 to 128 range. Users of hunks must realize that (*not (atom 'lispsval)*) will return true if *lispsval* is a hunk. Most lisp systems do not have a direct test for a list cell and instead use the above test and assume that a true result means *lispsval* is a list cell. In FRANZ LISP you can use *dtptr* to check for a list cell. Although hunks are not list cells, you can still access the first two hunk elements with *cdr* and *car* and you can access any hunk element with *cxr*<sup>†</sup>. You can set the value of the first two elements of a hunk with *rplacd* and *rplaca* and you can set the value of any element of the hunk with *rplacx*. A hunk is printed by printing its contents surrounded by { and }. However a hunk cannot be read in this way in the standard lisp system. It is easy to write a reader macro to do this if desired.

**1.2.13. other** Occasionally, you can obtain a pointer to storage not allocated by the lisp system. One example of this is the entry field of those FRANZ LISP functions written in C. Such objects are classified as of type **other**. Foreign functions which call malloc to allocate their own space, may also inadvertently create such objects. The garbage collector is supposed to ignore such objects.

**1.3. Documentation** The conventions used in the following chapters were designed to give a great deal of information in a brief space. The first line of a function description contains the function name in **bold face** and then lists the arguments, if any. The arguments all have names which begin with a letter or letters and an underscore. The letter(s) gives the allowable type(s) for that argument according to this table.

Letter	Allowable type(s)
g	any type
s	symbol (although nil may not be allowed)
t	string
l	list (although nil may be allowed)
n	number (fixnum, flonum, bignum)
i	integer (fixnum, bignum)
x	fixnum
b	bignum
f	flonum
u	function type (either binary or lambda body)
y	binary
v	vector
V	vectori
a	array
e	value
p	port (or nil)
h	hunk

In the first line of a function description, those arguments preceded by a quote mark are evaluated

---

<sup>†</sup>In a hunk, the function *cdr* references the first element and *car* the second.

(usually before the function is called). The quoting convention is used so that we can give a name to the result of evaluating the argument and we can describe the allowable types. If an argument is not quoted it does not mean that that argument will not be evaluated, but rather that if it is evaluated, the time at which it is evaluated will be specifically mentioned in the function description. Optional arguments are surrounded by square brackets. An ellipsis (...) means zero or more occurrences of an argument of the directly preceding type.

## CHAPTER 2

### Data Structure Access

The following functions allow one to create and manipulate the various types of lisp data structures. Refer to §1.2 for details of the data structures known to FRANZ LISP.

#### 2.1. Lists

The following functions exist for the creation and manipulating of lists. Lists are composed of a linked list of objects called either 'list cells', 'cons cells' or 'dtptr cells'. Lists are normally terminated with the special symbol **nil**. **nil** is both a symbol and a representation for the empty list ().

##### 2.1.1. list creation

**(cons 'g\_arg1 'g\_arg2)**

RETURNS: a new list cell whose car is *g\_arg1* and whose cdr is *g\_arg2*.

**(xcons 'g\_arg1 'g\_arg2)**

EQUIVALENT TO: *(cons 'g\_arg2 'g\_arg1)*

**(ncons 'g\_arg)**

EQUIVALENT TO: *(cons 'g\_arg nil)*

**(list ['g\_arg1 ... ])**

RETURNS: a list whose elements are the *g\_argi*.

**(append 'l\_arg1 'l\_arg2)**

RETURNS: a list containing the elements of *l\_arg1* followed by *l\_arg2*.

NOTE: To generate the result, the top level list cells of *l\_arg1* are duplicated and the cdr of the last list cell is set to point to *l\_arg2*. Thus this is an expensive operation if *l\_arg1* is large. See the descriptions of *nconc* and *tconc* for cheaper ways of doing the *append* if the list *l\_arg1* can be altered.

**(append1 'l\_arg1 'g\_arg2)**

RETURNS: a list like *l\_arg1* with *g\_arg2* as the last element.

NOTE: this is equivalent to *(append 'l\_arg1 (list 'g\_arg2))*.

---

```

; A common mistake is using append to add one element to the end of a list
[]> (append '(a b c d) 'e)
(a b c d . e)
; The user intended to say:
[]> (append '(a b c d) '(e))
(a b c d e)
; better is append!
[]> (append! '(a b c d) 'e)
(a b c d e)

```

---

**(quote! [g\_qformi] ...[! 'g\_iformi] ... [!! 'l\_formi] ...)**

RETURNS: The list resulting from the splicing and insertion process described below.

NOTE: *quote!* is the complement of the *list* function. *list* forms a list by evaluating each for in the argument list; evaluation is suppressed if the form is *quoted*. In *quote!*, each form is implicitly *quoted*. To be evaluated, a form must be preceded by one of the evaluate operations ! and !!. ! g\_iform evaluates g\_iform and the value is inserted in the place of the call; !! l\_form evaluates l\_form and the value is spliced into the place of the call.

‘Splicing in’ means that the parentheses surrounding the list are removed as the example below shows. Use of the evaluate operators can occur at any level in a form argument.

Another way to get the effect of the *quote!* function is to use the backquote character macro (see § 8.3.3).

---

```

(quote! cons ! (cons 1 2) 3) = (cons (1 . 2) 3)
(quote! 1 !! (list 2 3 4) 5) = (1 2 3 4 5)
(setq quoted 'eval)(quote! ! ((I am ! quoted))) = ((I am eval))
(quote! try ! '(this ! one)) = (try (this ! one))

```

---

**(bignum-to-list 'b\_arg)**

RETURNS: A list of the fixnums which are used to represent the bignum.

NOTE: the inverse of this function is *list-to-bignum*.

**(list-to-bignum 'l\_ints)**

WHERE: l\_ints is a list of fixnums.

RETURNS: a bignum constructed of the given fixnums.

NOTE: the inverse of this function is *bignum-to-list*.

**2.1.2. list predicates****(dtptr 'g\_arg)**

RETURNS: t iff g\_arg is a list cell.

NOTE: that (dtptr '()) is nil. The name **dtptr** is a contraction for “dotted pair”.

**(listp 'g\_arg)**

RETURNS: t iff g\_arg is a list object or nil.

**(tailp 'l\_x 'l\_y)**

RETURNS: l\_x, if a list cell eq to l\_x is found by *cdring* down l\_y zero or more times, nil otherwise.

---

```

[]> (setq x '(a b c d) y (cddr x))
(c d)
[]> (and (dtptr x) (listp x))      ; x and y are dtprs and lists
t
[]> (dtptr '())                  ; () is the same as nil and is not a dtpr
nil
[]> (listp '())                  ; however it is a list
t
[]> (tailp y x)
(c d)

```

---

**(length 'l\_arg)**

RETURNS: the number of elements in the top level of list l\_arg.

**2.1.3. list accessing****(car 'l\_arg)****(cdr 'l\_arg)**

RETURNS: cons cell. (*car* (*cons* x y)) is always x, (*cdr* (*cons* x y)) is always y. In FRANZ LISP, the cdr portion is located first in memory. This is hardly noticeable, and we mention it primarily as a curiosity.

**(c..r 'lh\_arg)**

WHERE: the .. represents any positive number of **a**'s and **d**'s.

RETURNS: the result of accessing the list structure in the way determined by the function name. The **a**'s and **d**'s are read from right to left, a **d** directing the access down the cdr part of the list cell and an **a** down the car part.

NOTE: lh\_arg may also be nil, and it is guaranteed that the car and cdr of nil is nil. If lh\_arg is a hunk, then (*car 'lh\_arg*) is the same as (*cxr 1 'lh\_arg*) and (*cdr 'lh\_arg*) is the same as (*cxr 0 'lh\_arg*).

It is generally hard to read and understand the context of functions with large strings of **a**'s and **d**'s, but these functions are supported by rapid accessing and open-compiling (see Chapter 12).

**(nth 'x\_index 'l\_list)**

RETURNS: the *nth* element of *l\_list*, assuming zero-based index. Thus *(nth 0 l\_list)* is the same as *(car l\_list)*. *nth* is both a function, and a compiler macro, so that more efficient code might be generated than for *nthelem* (described below).

NOTE: If *x\_arg1* is non-positive or greater than the length of the list, *nil* is returned.

**(nthcdr 'x\_index 'l\_list)**

RETURNS: the result of *cdring* down the list *l\_list* *x\_index* times.

NOTE: If *x\_index* is less than 0, then *(cons nil 'l\_list)* is returned.

**(nthelem 'x\_arg1 'l\_arg2)**

RETURNS: The *x\_arg1*'*st* element of the list *l\_arg2*.

NOTE: This function comes from the PDP-11 Lisp system.

**(last 'l\_arg)**

RETURNS: the last list cell in the list *l\_arg*.

EXAMPLE: *last* does NOT return the last element of a list!

*(last '(a b)) = (b)*

**(ldiff 'l\_x 'l\_y)**

RETURNS: a list of all elements in *l\_x* but not in *l\_y*, i.e., the list difference of *l\_x* and *l\_y*.

NOTE: *l\_y* must be a tail of *l\_x*, i.e., *eq* to the result of applying some number of *cdr*'s to *l\_x*. Note that the value of *ldiff* is always new list structure unless *l\_y* is *nil*, in which case *(ldiff l\_x nil)* is *l\_x* itself. If *l\_y* is not a tail of *l\_x*, *ldiff* generates an error.

EXAMPLE: *(ldiff 'l\_x (member 'g\_foo 'l\_x))* gives all elements in *l\_x* up to the first *g\_foo*.

**2.1.4. list manipulation****(rplaca 'lh\_arg1 'g\_arg2)**

RETURNS: the modified *lh\_arg1*.

SIDE EFFECT: the *car* of *lh\_arg1* is set to *g\_arg2*. If *lh\_arg1* is a hunk then the second element of the hunk is set to *g\_arg2*.

**(rplacd 'lh\_arg1 'g\_arg2)**

RETURNS: the modified *lh\_arg1*.

SIDE EFFECT: the *cdr* of *lh\_arg1* is set to *g\_arg2*. If *lh\_arg1* is a hunk then the first element of the hunk is set to *g\_arg2*.

**(attach 'g\_x 'l\_l)**

RETURNS: *l\_l* whose *car* is now *g\_x*, whose *cadr* is the original (*car l\_l*), and whose *cddr* is the original (*cdr l\_l*).

NOTE: what happens is that *g\_x* is added to the beginning of list *l\_l* yet maintaining the same list cell at the beginning of the list.

**(delete 'g\_val 'l\_list ['x\_count])**

RETURNS: the result of splicing *g\_val* from the top level of *l\_list* no more than *x\_count* times.

NOTE: *x\_count* defaults to a very large number, thus if *x\_count* is not given, all occurrences of *g\_val* are removed from the top level of *l\_list*. *g\_val* is compared with successive *car*'s of *l\_list* using the function *equal*.

SIDE EFFECT: *l\_list* is modified using *rplacd*, no new list cells are used.

**(delq 'g\_val 'l\_list ['x\_count])****(dremove 'g\_val 'l\_list ['x\_count])**

RETURNS: the result of splicing *g\_val* from the top level of *l\_list* no more than *x\_count* times.

NOTE: *delq* (and *dremove*) are the same as *delete* except that *eq* is used for comparison instead of *equal*.

---

```
; note that you should use the value returned by delete or delq
; and not assume that g_val will always show the deletions.
; For example
```

```
□> (setq test '(a b c a d e))
(a b c a d e)
□> (delete 'a test)
(b c d e) ; the value returned is what we would expect
□> test
(a b c d e) ; but test still has the first a in the list!
```

---

**(remq 'g\_x 'l\_l ['x\_count])****(remove 'g\_x 'l\_l)**

RETURNS: a *copy* of *l\_l* with all top level elements *equal* to *g\_x* removed. *remq* uses *eq* instead of *equal* for comparisons.

NOTE: *remove* does not modify its arguments like *delete*, and *delq* do.

**(insert 'g\_object 'l\_list 'u\_comparefn 'g\_nodups)**

RETURNS: a list consisting of *l\_list* with *g\_object* destructively inserted in a place determined by the ordering function *u\_comparefn*.

NOTE: (*comparefn 'g\_x 'g\_y*) should return something non-*nil* if *g\_x* can precede *g\_y* in sorted order, *nil* if *g\_y* must precede *g\_x*. If *u\_comparefn* is *nil*, alphabetical order will be used. If *g\_nodups* is non-*nil*, an element will not be inserted if an equal element is already in the list. *insert* does binary search to determine where to insert the new element.

**(merge** 'l\_data1 'l\_data2 'u\_comparefn)

RETURNS: the merged list of the two input sorted lists l\_data1 and l\_data1 using binary comparison function u\_comparefn.

NOTE: (*comparefn* 'g\_x 'g\_y) should return something non-nil if g\_x can precede g\_y in sorted order, nil if g\_y must precede g\_x. If u\_comparefn is nil, alphabetical order will be used. u\_comparefn should be thought of as "less than or equal". *merge* changes both of its data arguments.

**(subst** 'g\_x 'g\_y 'l\_s)

**(dsbst** 'g\_x 'g\_y 'l\_s)

RETURNS: the result of substituting g\_x for all *equal* occurrences of g\_y at all levels in l\_s.

NOTE: If g\_y is a symbol, *eq* will be used for comparisons. The function *subst* does not modify l\_s but the function *dsbst* (destructive substitution) does.

**(lsubst** 'l\_x 'g\_y 'l\_s)

RETURNS: a copy of l\_s with l\_x spliced in for every occurrence of g\_y at all levels. Splicing in means that the parentheses surrounding the list l\_x are removed as the example below shows.

---

```

[]> (subst '(a b c) 'x '(x y z (x y z) (x y z)))
((a b c) y z ((a b c) y z) ((a b c) y z))
[]> (lsubst '(a b c) 'x '(x y z (x y z) (x y z)))
(a b c y z (a b c y z) (a b c y z))

```

---

**(subpair** 'l\_old 'l\_new 'l\_expr)

WHERE: there are the same number of elements in l\_old as l\_new.

RETURNS: the list l\_expr with all occurrences of a object in l\_old replaced by the corresponding one in l\_new. When a substitution is made, a copy of the value to substitute in is not made.

EXAMPLE: (*subpair* '(a c) (x y) '(a b c d)) = (x b y d)

**(nconc** 'l\_arg1 'l\_arg2 ['l\_arg3 ...])

RETURNS: A list consisting of the elements of l\_arg1 followed by the elements of l\_arg2 followed by l\_arg3 and so on.

NOTE: The *cdr* of the last list cell of l\_argi is changed to point to l\_argi+1.

---

; *nconc* is faster than *append* because it doesn't allocate new list cells.

```
□> (setq lis1 '(a b c))
```

```
(a b c)
```

```
□> (setq lis2 '(d e f))
```

```
(d e f)
```

```
□> (append lis1 lis2)
```

```
(a b c d e f)
```

```
□> lis1
```

```
(a b c) ; note that lis1 has not been changed by append
```

```
□> (nconc lis1 lis2)
```

```
(a b c d e f) ; nconc returns the same value as append
```

```
□> lis1
```

```
(a b c d e f) ; but in doing so alters lis1
```

---

**(reverse 'l\_arg)**

**(nreverse 'l\_arg)**

RETURNS: the list *l\_arg* with the elements at the top level in reverse order.

NOTE: The function *nreverse* does the reversal in place, that is the list structure is modified.

**(nreconc 'l\_arg 'g\_arg)**

EQUIVALENT TO: *(nconc (nreverse 'l\_arg) 'g\_arg)*

## 2.2. Predicates

The following functions test for properties of data objects. When the result of the test is either 'false' or 'true', then **nil** will be returned for 'false' and something other than **nil** (often **t**) will be returned for 'true'.

**(arrayp 'g\_arg)**

RETURNS: **t** iff *g\_arg* is of type array.

**(atom 'g\_arg)**

RETURNS: **t** iff *g\_arg* is not a list or hunk object.

NOTE: *(atom '())* returns **t**.

**(bcdp 'g\_arg)**

RETURNS: **t** iff *g\_arg* is a data object of type binary.

NOTE: This function is a throwback to the PDP-11 Lisp system. The name stands for binary code predicate.

**(bigp 'g\_arg)**

RETURNS: t iff g\_arg is a bignum.

**(dtp 'g\_arg)**

RETURNS: t iff g\_arg is a list cell.

NOTE: that (dtp '()) is nil.

**(hunkp 'g\_arg)**

RETURNS: t iff g\_arg is a hunk.

**(listp 'g\_arg)**

RETURNS: t iff g\_arg is a list object or nil.

**(stringp 'g\_arg)**

RETURNS: t iff g\_arg is a string.

**(symbolp 'g\_arg)**

RETURNS: t iff g\_arg is a symbol.

**(valuep 'g\_arg)**

RETURNS: t iff g\_arg is a value cell

**(vectorp 'v\_vector)**

RETURNS: t iff the argument is a vector.

**(vectorip 'v\_vector)**

RETURNS: t iff the argument is an immediate-vector.

**(type 'g\_arg)****(typep 'g\_arg)**

RETURNS: a symbol whose pname describes the type of g\_arg.

**(signp s\_test 'g\_val)**

RETURNS: t iff g\_val is a number and the given test s\_test on g\_val returns true.

NOTE: The fact that *signp* simply returns nil if g\_val is not a number is probably the most important reason that *signp* is used. The permitted values for s\_test and what they mean are given in this table.

s_test	tested
l	g_val < 0
le	g_val ≤ 0
e	g_val = 0
n	g_val ≥ 0
ge	g_val ≥ 0
g	g_val > 0

**(eq 'g\_arg1 'g\_arg2)**

RETURNS: t if g\_arg1 and g\_arg2 are the exact same lisp object.

NOTE: *Eq* simply tests if g\_arg1 and g\_arg2 are located in the exact same place in memory. Lisp objects which print the same are not necessarily *eq*. The only objects guaranteed to be *eq* are interned symbols with the same print name. [Unless a symbol is created in a special way (such as with *uconcat* or *maknam*) it will be interned.]

**(neq 'g\_x 'g\_y)**

RETURNS: t if g\_x is not *eq* to g\_y, otherwise nil.

**(equal 'g\_arg1 'g\_arg2)**

**(eqstr 'g\_arg1 'g\_arg2)**

RETURNS: t iff g\_arg1 and g\_arg2 have the same structure as described below.

NOTE: g\_arg and g\_arg2 are *equal* if

- (1) they are *eq*.
- (2) they are both fixnums with the same value
- (3) they are both flonums with the same value
- (4) they are both bignums with the same value
- (5) they are both strings and are identical.
- (6) they are both lists and their cars and cdrs are *equal*.

---

```

; eq is much faster than equal, especially in compiled code,
; however you cannot use eq to test for equality of numbers outside
; of the range -1024 to 1023. equal will always work.
[]> (eq 1023 1023)
t
[]> (eq 1024 1024)
nil
[]> (equal 1024 1024)
t

```

---

**(not 'g\_arg)**

**(null 'g\_arg)**

RETURNS: t iff g\_arg is nil.

**(member 'g\_arg1 'l\_arg2)**

**(memq 'g\_arg1 'l\_arg2)**

RETURNS: that part of the `l_arg2` beginning with the first occurrence of `g_arg1`. If `g_arg1` is not in the top level of `l_arg2`, `nil` is returned.

NOTE: *member* tests for equality with *equal*, *memq* tests for equality with *eq*.

### 2.3. Symbols and Strings

In many of the following functions the distinction between symbols and strings is somewhat blurred. To remind ourselves of the difference, a string is a null terminated sequence of characters, stored as compactly as possible. Strings are used as constants in FRANZ LISP. They *eval* to themselves. A symbol has additional structure: a value, property list, function binding, as well as its external representation (or print-name). If a symbol is given to one of the string manipulation functions below, its print name will be used as the string.

Another popular way to represent strings in Lisp is as a list of fixnums which represent characters. The suffix 'n' to a string manipulation function indicates that it returns a string in this form.

#### 2.3.1. symbol and string creation

**(concat ['stn\_arg1 ... ])**

**(uconcat ['stn\_arg1 ... ])**

RETURNS: a symbol whose print name is the result of concatenating the print names, string characters or numerical representations of the `sn_argi`.

NOTE: If no arguments are given, a symbol with a null pname is returned. *concat* places the symbol created on the oblist, the function *uconcat* does the same thing but does not place the new symbol on the oblist.

EXAMPLE: `(concat 'abc (add 3 4) "def") = abc7def`

**(concatl 'l\_arg)**

EQUIVALENT TO: `(apply 'concat 'l_arg)`

**(implode 'l\_arg)**

**(maknam 'l\_arg)**

WHERE: `l_arg` is a list of symbols, strings and small fixnums.

RETURNS: The symbol whose print name is the result of concatenating the first characters of the print names of the symbols and strings in the list. Any fixnums are converted to the equivalent ascii character. In order to concatenate entire strings or print names, use the function *concat*.

NOTE: *implode* interns the symbol it creates, *maknam* does not.

**(gensym** [*'s\_leader*])

RETURNS: a new uninterned atom beginning with the first character of *s\_leader*'s pname, or beginning with *g* if *s\_leader* is not given.

NOTE: The symbol looks like *x0nnnnn* where *x* is *s\_leader*'s first character and *nnnnn* is the number of times you have called *gensym*.

**(copysymbol** *'s\_arg* *'g\_pred*)

RETURNS: an uninterned symbol with the same print name as *s\_arg*. If *g\_pred* is non nil, then the value, function binding and property list of the new symbol are made *eq* to those of *s\_arg*.

**(ascii** *'x\_charnum*)

WHERE: *x\_charnum* is between 0 and 255.

RETURNS: a symbol whose print name is the single character whose fixnum representation is *x\_charnum*.

**(intern** *'s\_arg*)

RETURNS: *s\_arg*

SIDE EFFECT: *s\_arg* is put on the oblist if it is not already there.

**(remob** *'s\_symbol*)

RETURNS: *s\_symbol*

SIDE EFFECT: *s\_symbol* is removed from the oblist.

**(rematom** *'s\_arg*)

RETURNS: *t* if *s\_arg* is indeed an atom.

SIDE EFFECT: *s\_arg* is put on the free atoms list, effectively reclaiming an atom cell.

NOTE: This function does *not* check to see if *s\_arg* is on the oblist or is referenced anywhere. Thus calling *rematom* on an atom in the oblist may result in disaster when that atom cell is reused!

**2.3.2. string and symbol predicates****(boundp** *'s\_name*)

RETURNS: *nil* if *s\_name* is unbound: that is, it has never been given a value. If *x\_name* has the value *g\_val*, then (*nil . g\_val*) is returned. See also *makunbound*.

**(alphalessp** *'st\_arg1* *'st\_arg2*)

RETURNS: *t* iff the 'name' of *st\_arg1* is alphabetically less than the name of *st\_arg2*. If *st\_arg* is a symbol then its 'name' is its print name. If *st\_arg* is a string, then its 'name' is the string itself.

**2.3.3. symbol and string accessing**

**(symeval 's\_arg)**

RETURNS: the value of symbol *s\_arg*.

NOTE: It is illegal to ask for the value of an unbound symbol. This function has the same effect as *eval*, but compiles into much more efficient code.

**(get\_pname 's\_arg)**

RETURNS: the string which is the print name of *s\_arg*.

**(plist 's\_arg)**

RETURNS: the property list of *s\_arg*.

**(getd 's\_arg)**

RETURNS: the function definition of *s\_arg* or nil if there is no function definition.

NOTE: the function definition may turn out to be an array header.

**(getchar 's\_arg 'x\_index)**

**(nthchar 's\_arg 'x\_index)**

**(getcharn 's\_arg 'x\_index)**

RETURNS: the *x\_index**th* character of the print name of *s\_arg* or nil if *x\_index* is less than 1 or greater than the length of *s\_arg*'s print name.

NOTE: *getchar* and *nthchar* return a symbol with a single character print name, *getcharn* returns the fixnum representation of the character.

**(substring 'st\_string 'x\_index ['x\_length])**

**(substringn 'st\_string 'x\_index ['x\_length])**

RETURNS: a string of length at most *x\_length* starting at *x\_index**th* character in the string.

NOTE: If *x\_length* is not given, all of the characters for *x\_index* to the end of the string are returned. If *x\_index* is negative the string begins at the *x\_index**th* character from the end. If *x\_index* is out of bounds, nil is returned.

NOTE: *substring* returns a list of symbols, *substringn* returns a list of fixnums. If *substringn* is given a 0 *x\_length* argument then a single fixnum which is the *x\_index**th* character is returned.

### 2.3.4. symbol and string manipulation

**(set 's\_arg1 'g\_arg2)**

RETURNS: *g\_arg2*.

SIDE EFFECT: the value of *s\_arg1* is set to *g\_arg2*.

**(setq s\_atm1 'g\_val1 [ s\_atm2 'g\_val2 ... ... ])**

WHERE: the arguments are pairs of atom names and expressions.

RETURNS: the last *g\_vali*.

SIDE EFFECT: each *s\_atmi* is set to have the value *g\_vali*.

NOTE: *set* evaluates all of its arguments, *setq* does not evaluate the *s\_atmi*.

**(desetq** *sl\_pattern1* 'g\_exp1 [... ...])

RETURNS: *g\_expn*

SIDE EFFECT: This acts just like *setq* if all the *sl\_patterni* are symbols. If *sl\_patterni* is a list then it is a template which should have the same structure as *g\_expi*. The symbols in *sl\_pattern* are assigned to the corresponding parts of *g\_exp*. (See also *setf*)

EXAMPLE: *(desetq (a b (c . d)) '(1 2 (3 4 5)))*  
 sets a to 1, b to 2, c to 3, and d to (4 5).

**(setplist** 's\_atm 'l\_plist)

RETURNS: *l\_plist*.

SIDE EFFECT: the property list of *s\_atm* is set to *l\_plist*.

**(makunbound** 's\_arg)

RETURNS: *s\_arg*

SIDE EFFECT: the value of *s\_arg* is made 'unbound'. If the interpreter attempts to evaluate *s\_arg* before it is again given a value, an unbound variable error will occur.

**(aexplode** 's\_arg)

**(explode** 'g\_arg)

**(aexplodec** 's\_arg)

**(explodec** 'g\_arg)

**(aexploden** 's\_arg)

**(exploden** 'g\_arg)

RETURNS: a list of the characters used to print out *s\_arg* or *g\_arg*.

NOTE: The functions beginning with 'a' are internal functions which are limited to symbol arguments. The functions *aexplode* and *explode* return a list of characters which *print* would use to print the argument. These characters include all necessary escape characters. Functions *aexplodec* and *explodec* return a list of characters which *patom* would use to print the argument (i.e. no escape characters). Functions *aexploden* and *exploden* are similar to *aexplodec* and *explodec* except that a list of fixnum equivalents of characters are returned.

---

```

[]> (setq x 'lquote this \ ok?)
lquote this \ ok?
[]> (explode x)
(q u o t e \ | | t h i s \ | | \ | | \ | | o k ?)
; note that \ just means the single character: backslash.
; and | just means the single character: vertical bar
; and | | means the single character: space

[]> (explodec x)
(q u o t e | | t h i s | | \ | | o k ?)
[]> (exploden x)
(113 117 111 116 101 32 116 104 105 115 32 124 32 111 107 63)
    
```

---

## 2.4. Vectors

See Chapter 9 for a discussion of vectors. They are less efficient than hunks but more efficient than arrays.

### 2.4.1. vector creation

**(new-vector** 'x\_size ['g\_fill ['g\_prop]])

RETURNS: A **vector** of length x\_size. Each data entry is initialized to g\_fill, or to nil, if the argument g\_fill is not present. The vector's property is set to g\_prop, or to nil, by default.

**(new-vectori-byte** 'x\_size ['g\_fill ['g\_prop]])

**(new-vectori-word** 'x\_size ['g\_fill ['g\_prop]])

**(new-vectori-long** 'x\_size ['g\_fill ['g\_prop]])

RETURNS: A **vectori** with x\_size elements in it. The actual memory requirement is two long words + x\_size\*(n bytes), where n is 1 for new-vector-byte, 2 for new-vector-word, or 4 for new-vectori-long. Each data entry is initialized to g\_fill, or to zero, if the argument g\_fill is not present. The vector's property is set to g\_prop, or nil, by default.

Vectors may be created by specifying multiple initial values:

**(vector** ['g\_val0 'g\_val1 ...])

RETURNS: a **vector**, with as many data elements as there are arguments. It is quite possible to have a vector with no data elements. The vector's property will be a null list.

**(vectori-byte** ['x\_val0 'x\_val2 ...])

**(vectori-word** ['x\_val0 'x\_val2 ...])

**(vectori-long** ['x\_val0 'x\_val2 ...])

RETURNS: a **vectori**, with as many data elements as there are arguments. The arguments are required to be fixnums. Only the low order byte or word is used in the case of vectori-byte and vectori-word. The vector's property will be null.

### 2.4.2. vector reference

**(vref** 'v\_vect 'x\_index)

**(vrefi-byte** 'V\_vect 'x\_bindex)

**(vrefi-word** 'V\_vect 'x\_windex)

**(vrefi-long** 'V\_vect 'x\_lindex)

RETURNS: the desired data element from a vector. The indices must be fixnums. Indexing is zero-based. The vrefi functions sign extend the data.

**(vprop 'Vv\_vect)**

RETURNS: The Lisp property associated with a vector.

**(vget 'Vv\_vect 'g\_ind)**

RETURNS: The value stored under `g_ind` if the Lisp property associated with `'Vv_vect` is a disembodied property list.

**(vsize 'Vv\_vect)**

**(vsize-byte 'Vv\_vect)**

**(vsize-word 'Vv\_vect)**

RETURNS: the number of data elements in the vector. For immediate-vectors, the functions `vsize-byte` and `vsize-word` return the number of data elements, if one thinks of the binary data as being comprised of bytes or words.

### 2.4.3. vector modification

**(vset 'v\_vect 'x\_index 'g\_val)**

**(vseti-byte 'Vv\_vect 'x\_bindex 'x\_val)**

**(vseti-word 'Vv\_vect 'x\_windex 'x\_val)**

**(vseti-long 'Vv\_vect 'x\_lindex 'x\_val)**

RETURNS: the datum.

SIDE EFFECT: The indexed element of the vector is set to the value. As noted above, for `vseti-word` and `vseti-byte`, the index is construed as the number of the data element within the vector. It is not a byte address. Also, for those two functions, the low order byte or word of `x_val` is what is stored.

**(vsetprop 'Vv\_vect 'g\_value)**

RETURNS: `g_value`. This should be either a symbol or a disembodied property list whose *car* is a symbol identifying the type of the vector.

SIDE EFFECT: the property list of `Vv_vect` is set to `g_value`.

**(vputprop 'Vv\_vect 'g\_value 'g\_ind)**

RETURNS: `g_value`.

SIDE EFFECT: If the vector property of `Vv_vect` is a disembodied property list, then `vputprop` adds the value `g_value` under the indicator `g_ind`. Otherwise, the old vector property is made the first element of the list.

## 2.5. Arrays

See Chapter 9 for a complete description of arrays. Some of these functions are part of a Maclisp array compatibility package representing only one simple way of using the array structure of FRANZ LISP.

### 2.5.1. array creation

**(marray 'g\_data 's\_access 'g\_aux 'x\_length 'x\_delta)**

RETURNS: an array type with the fields set up from the above arguments in the obvious way (see § 1.2.10).

**(\*array 's\_name 's\_type 'x\_dim1 ... 'x\_dimn)**

**(array s\_name s\_type x\_dim1 ... x\_dimn)**

WHERE: s\_type may be one of t, nil, fixnum, flonum, fixnum-block and flonum-block.

RETURNS: an array of type s\_type with n dimensions of extents given by the x\_dimi.

SIDE EFFECT: If s\_name is non nil, the function definition of s\_name is set to the array structure returned.

NOTE: These functions create a Maclisp compatible array. In FRANZ LISP arrays of type t, nil, fixnum and flonum are equivalent and the elements of these arrays can be any type of lisp object. Fixnum-block and flonum-block arrays are restricted to fixnums and flonums respectively and are used mainly to communicate with foreign functions (see §8.5).

NOTE: \*array evaluates its arguments, array does not.

### 2.5.2. array predicate

**(arrayp 'g\_arg)**

RETURNS: t iff g\_arg is of type array.

### 2.5.3. array accessors

**(getaccess 'a\_array)**

**(getaux 'a\_array)**

**(getdelta 'a\_array)**

**(getdata 'a\_array)**

**(getlength 'a\_array)**

RETURNS: the field of the array object a\_array given by the function name.

**(arrayref 'a\_name 'x\_ind)**

RETURNS: the x\_indth element of the array object a\_name. x\_ind of zero accesses the first element.

NOTE: arrayref uses the data, length and delta fields of a\_name to determine which object to return.

**(arraycall s\_type 'as\_array 'x\_ind1 ...)**

RETURNS: the element selected by the indices from the array a\_array of type s\_type.

NOTE: If as\_array is a symbol then the function binding of this symbol should contain an array object.

s\_type is ignored by arraycall but is included for compatibility with Maclisp.

**(arraydims 's\_name)**

RETURNS: a list of the type and bounds of the array s\_name.

**(listarray 'sa\_array ['x\_elements])**

RETURNS: a list of all of the elements in array sa\_array. If x\_elements is given, then only the first x\_elements are returned.

---

```

; We will create a 3 by 4 array of general lisp objects
[]> (array ernie t 3 4)
array[12]

; the array header is stored in the function definition slot of the
; symbol ernie
[]> (arrayp (getd 'ernie))
t
[]> (arraydims (getd 'ernie))
(t 3 4)

; store in ernie[2][2] the list (test list)
[]> (store (ernie 2 2) '(test list))
(test list)

; check to see if it is there
[]> (ernie 2 2)
(test list)

; now use the low level function arrayref to find the same element
; arrays are 0 based and row-major (the last subscript varies the fastest)
; thus element [2][2] is the 10th element , (starting at 0).
[]> (arrayref (getd 'ernie) 10)
(ptr to)(test list) ; the result is a value cell (thus the (ptr to))

```

---

#### 2.5.4. array manipulation

**(putaccess 'a\_array 'su\_func)**

**(putaux 'a\_array 'g\_aux)**

**(putdata 'a\_array 'g\_arg)**

**(putdelta 'a\_array 'x\_delta)**

**(putlength 'a\_array 'x\_length)**

RETURNS: the second argument to the function.

SIDE EFFECT: The field of the array object given by the function name is replaced by the second argument to the function.

**(store 'l\_arexp 'g\_val)**

WHERE: l\_arexp is an expression which references an array element.

RETURNS: g\_val

SIDE EFFECT: the array location which contains the element which l\_arexp references is changed to contain g\_val.

**(fillarray 's\_array 'l\_itms)**

RETURNS: s\_array

SIDE EFFECT: the array s\_array is filled with elements from l\_itms. If there are not enough elements in l\_itms to fill the entire array, then the last element of l\_itms is used to fill the remaining parts of the array.

## 2.6. Hunks

Hunks are vector-like objects whose size can range from 1 to 128 elements. Internally, hunks are allocated in sizes which are powers of 2. In order to create hunks of a given size, a hunk with at least that many elements is allocated and a distinguished symbol EMPTY is placed in those elements not requested. Most hunk functions respect those distinguished symbols, but there are two (*\*makhunk* and *\*rplacx*) which will overwrite the distinguished symbol.

### 2.6.1. hunk creation

**(hunk 'g\_val1 ['g\_val2 ... 'g\_valn])**

RETURNS: a hunk of length n whose elements are initialized to the g\_vali.

NOTE: the maximum size of a hunk is 128.

EXAMPLE: (*hunk 4 'sharp 'keys*) = {4 sharp keys}

**(makhunk 'xl\_arg)**

RETURNS: a hunk of length xl\_arg initialized to all nils if xl\_arg is a fixnum. If xl\_arg is a list, then we return a hunk of size (*length 'xl\_arg*) initialized to the elements in xl\_arg.

NOTE: (*makhunk '(a b c)*) is equivalent to (*hunk 'a 'b 'c*).

EXAMPLE: (*makhunk 4*) = {nil nil nil nil}

**(\*makhunk 'x\_arg)**

RETURNS: a hunk of size  $2^{x\_arg}$  initialized to EMPTY.

NOTE: This is only to be used by such functions as *hunk* and *makhunk* which create and initialize hunks for users.

### 2.6.2. hunk accessor

**(cxl 'x\_ind 'h\_hunk)**

RETURNS: element *x\_ind* (starting at 0) of hunk *h\_hunk*.

**(hunk-to-list 'h\_hunk)**

RETURNS: a list consisting of the elements of *h\_hunk*.

### 2.6.3. hunk manipulators

**(rplacx 'x\_ind 'h\_hunk 'g\_val)**

**(\*rplacx 'x\_ind 'h\_hunk 'g\_val)**

RETURNS: *h\_hunk*

SIDE EFFECT: Element *x\_ind* (starting at 0) of *h\_hunk* is set to *g\_val*.

NOTE: *rplacx* will not modify one of the distinguished (EMPTY) elements whereas *\*rplacx* will.

**(hunksize 'h\_arg)**

RETURNS: the size of the hunk *h\_arg*.

EXAMPLE: (*hunksize (hunk 1 2 3)*) = 3

## 2.7. Bcds

A bcd object contains a pointer to compiled code and to the type of function object the compiled code represents.

**(getdisc 'y\_bcd)**

**(getentry 'y\_bcd)**

RETURNS: the field of the bcd object given by the function name.

**(putdisc 'y\_func 's\_discipline)**

RETURNS: *s\_discipline*

SIDE EFFECT: Sets the discipline field of *y\_func* to *s\_discipline*.

## 2.8. Structures

There are three common structures constructed out of list cells: the assoc list, the property list and the tconc list. The functions below manipulate these structures.

### 2.8.1. assoc list

An 'assoc list' (or alist) is a common lisp data structure. It has the form  
(key1 . value1) (key2 . value2) (key3 . value3) ... (keyn . valuen)

**(assoc 'g\_arg1 'l\_arg2)**

**(assq 'g\_arg1 'l\_arg2)**

RETURNS: the first top level element of *l\_arg2* whose *car* is *equal* (with *assoc*) or *eq* (with *assq*) to *g\_arg1*.

NOTE: Usually *l\_arg2* has an *a-list* structure and *g\_arg1* acts as key.

**(sassoc 'g\_arg1 'l\_arg2 'sl\_func)**

RETURNS: the result of *(cond ((assoc 'g\_arg 'l\_arg2) (apply 'sl\_func nil)))*

NOTE: *sassoc* is written as a macro.

**(sassq 'g\_arg1 'l\_arg2 'sl\_func)**

RETURNS: the result of *(cond ((assq 'g\_arg 'l\_arg2) (apply 'sl\_func nil)))*

NOTE: *sassq* is written as a macro.

---

```
; assoc or assq is given a key and an assoc list and returns
; the key and value item if it exists, they differ only in how they test
; for equality of the keys.
```

```
[]> (setq alist '((alpha . a) ((complex key) . b) (junk . x)))
((alpha . a) ((complex key) . b) (junk . x))
```

```
; we should use assq when the key is an atom
```

```
[]> (assq 'alpha alist)
(alpha . a)
```

```
; but it may not work when the key is a list
```

```
[]> (assq '(complex key) alist)
nil
```

```
; however assoc will always work
```

```
[]> (assoc '(complex key) alist)
((complex key) . b)
```

---

**(sublis 'l\_alst 'l\_exp)**

WHERE: *l\_alst* is an *a-list*.

RETURNS: the list *l\_exp* with every occurrence of *key<sub>i</sub>* replaced by *val<sub>i</sub>*.

NOTE: new list structure is returned to prevent modification of *l\_exp*. When a substitution is made, a copy of the value to substitute in is not made.

### 2.8.2. property list

A property list consists of an alternating sequence of keys and values. Normally a property list is stored on a symbol. A list is a 'disembodied' property list if it contains an odd number of elements, the first of which is ignored.

**(plist 's\_name)**

RETURNS: the property list of s\_name.

**(setplist 's\_atm 'l\_plist)**

RETURNS: l\_plist.

SIDE EFFECT: the property list of s\_atm is set to l\_plist.

**(get 'ls\_name 'g\_ind)**

RETURNS: the value under indicator g\_ind in ls\_name's property list if ls\_name is a symbol.

NOTE: If there is no indicator g\_ind in ls\_name's property list nil is returned. If ls\_name is a list of an odd number of elements then it is a disembodied property list. *get* searches a disembodied property list by starting at its *cdr*, and comparing every other element with g\_ind, using *eq*.

**(getl 'ls\_name 'l\_indicators)**

RETURNS: the property list ls\_name beginning at the first indicator which is a member of the list l\_indicators, or nil if none of the indicators in l\_indicators are on ls\_name's property list.

NOTE: If ls\_name is a list, then it is assumed to be a disembodied property list.

**(putprop 'ls\_name 'g\_val 'g\_ind)**

**(defprop ls\_name g\_val g\_ind)**

RETURNS: g\_val.

SIDE EFFECT: Adds to the property list of ls\_name the value g\_val under the indicator g\_ind.

NOTE: *putprop* evaluates its arguments, *defprop* does not. ls\_name may be a disembodied property list, see *get*.

**(remprop 'ls\_name 'g\_ind)**

RETURNS: the portion of ls\_name's property list beginning with the property under the indicator g\_ind. If there is no g\_ind indicator in ls\_name's plist, nil is returned.

SIDE EFFECT: the value under indicator g\_ind and g\_ind itself is removed from the property list of ls\_name.

NOTE: ls\_name may be a disembodied property list, see *get*.

---

```

[]> (putprop 'xlate 'a 'alpha)
a
[]> (putprop 'xlate 'b 'beta)
b
[]> (plist 'xlate)
(alpha a beta b)
[]> (get 'xlate 'alpha)
a
; use of a disembodied property list:
[]> (get '(nil fateman rjf sklower kls foderaro jkf) 'sklower)
kls

```

---

**2.8.3. tconc structure**

A *tconc* structure is a special type of list designed to make it easy to add objects to the end. It consists of a list cell whose *car* points to a list of the elements added with *tconc* or *lconc* and whose *cdr* points to the last list cell of the list pointed to by the *car*.

**(tconc 'l\_ptr 'g\_x)**

WHERE: *l\_ptr* is a *tconc* structure.

RETURNS: *l\_ptr* with *g\_x* added to the end.

**(lconc 'l\_ptr 'l\_x)**

WHERE: *l\_ptr* is a *tconc* structure.

RETURNS: *l\_ptr* with the list *l\_x* spliced in at the end.

---

```
; A tconc structure can be initialized in two ways.
; nil can be given to tconc in which case tconc will generate
; a tconc structure.
```

```
□>(setq foo (tconc nil 1))
((1) 1)
```

```
; Since tconc destructively adds to
; the list, you can now add to foo without using setq again.
```

```
□>(tconc foo 2)
((1 2) 2)
□>foo
((1 2) 2)
```

```
; Another way to create a null tconc structure
; is to use (ncons nil).
```

```
□>(setq foo (ncons nil))
(nil)
□>(tconc foo 1)
((1) 1)
```

```
; now see what lconc can do
```

```
□>(lconc foo nil)
((1) 1) ; no change
□>(lconc foo '(2 3 4))
((1 2 3 4) 4)
```

---

**2.8.4. fclosures**

An *fclosure* is a functional object which admits some data manipulations. They are discussed in §8.4. Internally, they are constructed from vectors.

**(fclosure** 'l\_vars 'g\_funobj)

WHERE: l\_vars is a list of variables, g\_funobj is any object that can be funcalled (including, fclosures).

RETURNS: A vector which is the fclosure.

**(fclosure-alist** 'v\_fclosure)

RETURNS: An association list representing the variables in the fclosure. This is a snapshot of the current state of the fclosure. If the bindings in the fclosure are changed, any previously calculated results of *fclosure-alist* will not change.

**(fclosure-function** 'v\_fclosure)

RETURNS: the functional object part of the fclosure.

**(fclosurep** 'v\_fclosure)

RETURNS: t iff the argument is an fclosure.

**(symeval-in-fclosure** 'v\_fclosure 's\_symbol)

RETURNS: the current binding of a particular symbol in an fclosure.

**(set-in-fclosure** 'v\_fclosure 's\_symbol 'g\_newvalue)

RETURNS: g\_newvalue.

SIDE EFFECT: The variable s\_symbol is bound in the fclosure to g\_newvalue.

## 2.9. Random functions

The following functions don't fall into any of the classifications above.

**(bcdad** 's\_funcname)

RETURNS: a fixnum which is the address in memory where the function s\_funcname begins. If s\_funcname is not a machine coded function (binary) then *bcdad* returns nil.

**(copy** 'g\_arg)

RETURNS: A structure *equal* to g\_arg but with new list cells.

**(copyint\*** 'x\_arg)

RETURNS: a fixnum with the same value as x\_arg but in a freshly allocated cell.

**(cpy1** 'xvt\_arg)

RETURNS: a new cell of the same type as xvt\_arg with the same value as xvt\_arg.

**(getaddress 's\_entry1 's\_binder1 'st\_discipline1 [... .. ...])**

RETURNS: the binary object which s\_binder1's function field is set to.

NOTE: This looks in the running lisp's symbol table for a symbol with the same name as s\_entry<sub>i</sub>. It then creates a binary object whose entry field points to s\_entry<sub>i</sub> and whose discipline is st\_discipline<sub>i</sub>. This binary object is stored in the function field of s\_binder<sub>i</sub>. If st\_discipline<sub>i</sub> is nil, then "subroutine" is used by default. This is especially useful for *cfasl* users.

**(macroexpand 'g\_form)**

RETURNS: g\_form after all macros in it are expanded.

NOTE: This function will only macroexpand expressions which could be evaluated and it does not know about the special nlambdas such as *cond* and *do*, thus it misses many macro expansions.

**(ptr 'g\_arg)**

RETURNS: a value cell initialized to point to g\_arg.

**(quote g\_arg)**

RETURNS: g\_arg.

NOTE: the reader allows you to abbreviate (quote foo) as 'foo.

**(kwote 'g\_arg)**

RETURNS: (list (quote quote) g\_arg).

**(replace 'g\_arg1 'g\_arg2)**

WHERE: g\_arg1 and g\_arg2 must be the same type of lispval and not symbols or hunks.

RETURNS: g\_arg2.

SIDE EFFECT: The effect of *replace* is dependent on the type of the g\_arg<sub>i</sub> although one will notice a similarity in the effects. To understand what *replace* does to fixnum and flonum arguments, you must first understand that such numbers are 'boxed' in FRANZ LISP. What this means is that if the symbol x has a value 32412, then in memory the value element of x's symbol structure contains the address of another word of memory (called a box) with 32412 in it.

Thus, there are two ways of changing the value of x: the first is to change the value element of x's symbol structure to point to a word of memory with a different value. The second way is to change the value in the box which x points to. The former method is used almost all of the time, the latter is used very rarely and has the potential to cause great confusion. The function *replace* allows you to do the latter, i.e., to actually change the value in the box.

You should watch out for these situations. If you do (*setq y x*), then both x and y will point to the same box. If you now (*replace x 12345*), then y will also have the value 12345. And, in fact, there may be many other pointers to that box.

Another problem with replacing fixnums is that some boxes are read-only. The fixnums between -1024 and 1023 are stored in a read-only area and attempts to replace them will result in an "Illegal memory reference" error (see the description of *copyint*\* for a way around this problem).

For the other valid types, the effect of *replace* is easy to understand. The fields of g\_val1's structure are made eq to the corresponding fields of g\_val2's structure. For example, if x and y have lists as values then the effect of (*replace x y*) is the same as (*rplaca x (car y)*) and (*rplacd x (cdr y)*).

**(scons 'x\_arg 'bs\_rest)**

WHERE: `bs_rest` is a bignum or nil.

RETURNS: a bignum whose first bigit is `x_arg` and whose higher order bigits are `bs_rest`.

**(setf g\_refexpr 'g\_value)**

NOTE: *setf* is a generalization of *setq*. Information may be stored by binding variables, replacing entries of arrays, and vectors, or being put on property lists, among others. *Setf* will allow the user to store data into some location, by mentioning the operation used to refer to the location. Thus, the first argument may be partially evaluated, but only to the extent needed to calculate a reference. *setf* returns `g_value`. (Compare to *desetq*)

---

```
(setf x 3)      = (setq x 3)
(setf (car x) 3) = (rplaca x 3)
(setf (get foo 'bar) 3) = (putprop foo 3 'bar)
(setf (vref vector index) value) = (vset vector index value)
```

---

**(sort 'l\_data 'u\_comparefn)**

RETURNS: a list of the elements of `l_data` ordered by the comparison function `u_comparefn`.

SIDE EFFECT: the list `l_data` is modified rather than allocated in new storage.

NOTE: (*comparefn* 'g\_x 'g\_y) should return something non-nil if `g_x` can precede `g_y` in sorted order; nil if `g_y` must precede `g_x`. If `u_comparefn` is nil, alphabetical order will be used.

**(sortcar 'l\_list 'u\_comparefn)**

RETURNS: a list of the elements of `l_list` with the *car*'s ordered by the sort function `u_comparefn`.

SIDE EFFECT: the list `l_list` is modified rather than copied.

NOTE: Like *sort*, if `u_comparefn` is nil, alphabetical order will be used.

## CHAPTER 3

### Arithmetic Functions

This chapter describes FRANZ LISP's functions for doing arithmetic. Often the same function is known by many names. For example, *add* is also *plus*, and *sum*. This is caused by our desire to be compatible with other Lisps. The FRANZ LISP user should avoid using functions with names such as *+* and *-* unless their arguments are fixnums. The Lisp compiler takes advantage of these implicit declarations.

An attempt to divide or to generate a floating point result outside of the range of floating point numbers will cause a floating exception signal from the UNIX operating system. The user can catch and process this interrupt if desired (see the description of the *signal* function).

#### 3.1. Simple Arithmetic Functions

**(add** [*'n\_arg1* ...])  
**(plus** [*'n\_arg1* ...])  
**(sum** [*'n\_arg1* ...])  
**(+** [*'x\_arg1* ...])

RETURNS: the sum of the arguments. If no arguments are given, 0 is returned.

NOTE: if the size of the partial sum exceeds the limit of a fixnum, the partial sum will be converted to a bignum. If any of the arguments are flonums, the partial sum will be converted to a flonum when that argument is processed and the result will thus be a flonum. Currently, if in the process of doing the addition a bignum must be converted into a flonum an error message will result.

**(add1** *'n\_arg*)  
**(1+** *'x\_arg*)

RETURNS: its argument plus 1.

**(diff** [*'n\_arg1* ... ])  
**(difference** [*'n\_arg1* ... ])  
**(-)** [*'x\_arg1* ... ])

RETURNS: the result of subtracting from *n\_arg1* all subsequent arguments. If no arguments are given, 0 is returned.

NOTE: See the description of *add* for details on data type conversions and restrictions.

**(sub1 'n\_arg)**

**(1- 'x\_arg)**

RETURNS: its argument minus 1.

**(minus 'n\_arg)**

RETURNS: zero minus n\_arg.

**(product ['n\_arg1 ... ])**

**(times ['n\_arg1 ... ])**

**([\* 'x\_arg1 ... ])**

RETURNS: the product of all of its arguments. It returns 1 if there are no arguments.

NOTE: See the description of the function *add* for details and restrictions to the automatic data type coercion.

**(quotient ['n\_arg1 ...])**

**(/ ['x\_arg1 ...])**

RETURNS: the result of dividing the first argument by succeeding ones.

NOTE: If there are no arguments, 1 is returned. See the description of the function *add* for details and restrictions of data type coercion. A divide by zero will cause a floating exception interrupt -- see the description of the *signal* function.

**(\*quo 'i\_x 'i\_y)**

RETURNS: the integer part of  $i_x / i_y$ .

**(Divide 'i\_dividend 'i\_divisor)**

RETURNS: a list whose car is the quotient and whose cadr is the remainder of the division of  $i\_dividend$  by  $i\_divisor$ .

NOTE: this is restricted to integer division.

**(Emuldiv 'x\_fact1 'x\_fact2 'x\_addn 'x\_divisor)**

RETURNS: a list of the quotient and remainder of this operation:  
 $((x\_fact1 * x\_fact2) + (\text{sign extended } x\_addn) / x\_divisor$ .

NOTE: this is useful for creating a bignum arithmetic package in Lisp.

### 3.2. predicates

**(numberp 'g\_arg)**

**(numbp 'g\_arg)**

RETURNS: t iff  $g\_arg$  is a number (fixnum, flonum or bignum).

**(fixp 'g\_arg)**

RETURNS: t iff g\_arg is a fixnum or bignum.

**(floatp 'g\_arg)**

RETURNS: t iff g\_arg is a flonum.

**(evenp 'x\_arg)**

RETURNS: t iff x\_arg is even.

**(oddp 'x\_arg)**

RETURNS: t iff x\_arg is odd.

**(zerop 'g\_arg)**

RETURNS: t iff g\_arg is a number equal to 0.

**(onep 'g\_arg)**

RETURNS: t iff g\_arg is a number equal to 1.

**(plusp 'n\_arg)**

RETURNS: t iff n\_arg is greater than zero.

**(minusp 'g\_arg)**

RETURNS: t iff g\_arg is a negative number.

**(greaterp ['n\_arg1 ...])**

**(> 'fx\_arg1 'fx\_arg2)**

**(>& 'x\_arg1 'x\_arg2)**

RETURNS: t iff the arguments are in a strictly decreasing order.

NOTE: In functions *greaterp* and *>* the function *difference* is used to compare adjacent values. If any of the arguments are non-numbers, the error message will come from the *difference* function. The arguments to *>* must be fixnums or both flonums. The arguments to *>&* must both be fixnums.

**(lessp ['n\_arg1 ...])**

**(< 'fx\_arg1 'fx\_arg2)**

**(<& 'x\_arg1 'x\_arg2)**

RETURNS: t iff the arguments are in a strictly increasing order.

NOTE: In functions *lessp* and *<* the function *difference* is used to compare adjacent values. If any of the arguments are non numbers, the error message will come from the *difference* function. The arguments to *<* may be either fixnums or flonums but must be the same type. The arguments to *<&* must be fixnums.

(= 'fx\_arg1 'fx\_arg2)

(=& 'x\_arg1 'x\_arg2)

RETURNS: t iff the arguments have the same value. The arguments to = must be the either both fixnums or both flonums. The arguments to =& must be fixnums.

### 3.3. Trigonometric Functions

Some of these functions are taken from the host math library, and we take no further responsibility for their accuracy.

(cos 'fx\_angle)

RETURNS: the (flonum) cosine of fx\_angle (which is assumed to be in radians).

(sin 'fx\_angle)

RETURNS: the sine of fx\_angle (which is assumed to be in radians).

(acos 'fx\_arg)

RETURNS: the (flonum) arc cosine of fx\_arg in the range 0 to  $\pi$ .

(asin 'fx\_arg)

RETURNS: the (flonum) arc sine of fx\_arg in the range  $-\pi/2$  to  $\pi/2$ .

(atan 'fx\_arg1 'fx\_arg2)

RETURNS: the (flonum) arc tangent of fx\_arg1/fx\_arg2 in the range  $-\pi$  to  $\pi$ .

### 3.4. Bignum/Fixnum Manipulation

(haipart bx\_number x\_bits)

RETURNS: a fixnum (or bignum) which contains the x\_bits high bits of (abs bx\_number) if x\_bits is positive, otherwise it returns the (abs x\_bits) low bits of (abs bx\_number).

(haulong bx\_number)

RETURNS: the number of significant bits in bx\_number.

NOTE: the result is equal to the least integer greater to or equal to the base two logarithm of one plus the absolute value of bx\_number.

(bignum-leftshift bx\_arg x\_amount)

RETURNS: bx\_arg shifted left by x\_amount. If x\_amount is negative, bx\_arg will be shifted right by the magnitude of x\_amount.

NOTE: If bx\_arg is shifted right, it will be rounded to the nearest even number.

**(sticky-bignum-leftshift 'bx\_arg 'x\_amount)**

RETURNS: `bx_arg` shifted left by `x_amount`. If `x_amount` is negative, `bx_arg` will be shifted right by the magnitude of `x_amount` and rounded.

NOTE: sticky rounding is done this way: after shifting, the low order bit is changed to 1 if any 1's were shifted off to the right.

### 3.5. Bit Manipulation

**(boole 'x\_key 'x\_v1 'x\_v2 ...)**

RETURNS: the result of the bitwise boolean operation as described in the following table.

NOTE: If there are more than 3 arguments, then evaluation proceeds left to right with each partial result becoming the new value of `x_v1`. That is,

$(boole\ 'key\ 'v1\ 'v2\ 'v3) \equiv (boole\ 'key\ (boole\ 'key\ 'v1\ 'v2)\ 'v3)$ .

In the following table,  $\wedge$  represents bitwise and,  $+$  represents bitwise or,  $\oplus$  represents bitwise xor and  $\neg$  represents bitwise negation and is the highest precedence operator.

(boole 'key 'x 'y)								
key	0	1	2	3	4	5	6	7
result	0	$x \wedge y$	$\neg x \wedge y$	$y$	$x \neg \neg y$	$x$	$x \oplus y$	$x + y$
common names		and			bitclear		xor	or
key	8	9	10	11	12	13	14	15
result	$\neg (x + y)$	$\neg (x \oplus y)$	$\neg x$	$\neg x + y$	$\neg y$	$x + \neg y$	$\neg x + \neg y$	-1
common names	nor	equiv		implies			nand	

**(lsh 'x\_val 'x\_amt)**

RETURNS: `x_val` shifted left by `x_amt` if `x_amt` is positive. If `x_amt` is negative, then `lsh` returns `x_val` shifted right by the magnitude if `x_amt`.

NOTE: This always returns a fixnum even for those numbers whose magnitude is so large that they would normally be represented as a bignum, i.e. shifter bits are lost. For more general bit shifters, see *bignum-leftshift* and *sticky-bignum-leftshift*.

**(rot 'x\_val 'x\_amt)**

RETURNS: `x_val` rotated left by `x_amt` if `x_amt` is positive. If `x_amt` is negative, then `x_val` is rotated right by the magnitude of `x_amt`.

### 3.6. Other Functions

As noted above, some of the following functions are inherited from the host math library, with all their virtues and vices.

**(abs 'n\_arg)**

**(absval 'n\_arg)**

RETURNS: the absolute value of n\_arg.

**(exp 'fx\_arg)**

RETURNS:  $e$  raised to the fx\_arg power (flonum) .

**(expt 'n\_base 'n\_power)**

RETURNS: n\_base raised to the n\_power power.

NOTE: if either of the arguments are flonums, the calculation will be done using *log* and *exp*.

**(fact 'x\_arg)**

RETURNS: x\_arg factorial. (fixnum or bignum)

**(fix 'n\_arg)**

RETURNS: a fixnum as close as we can get to n\_arg.

NOTE: *fix* will round down. Currently, if n\_arg is a flonum larger than the size of a fixnum, this will fail.

**(float 'n\_arg)**

RETURNS: a flonum as close as we can get to n\_arg.

NOTE: if n\_arg is a bignum larger than the maximum size of a flonum, then a floating exception will occur.

**(log 'fx\_arg)**

RETURNS: the natural logarithm of fx\_arg.

**(max 'n\_arg1 ...)**

RETURNS: the maximum value in the list of arguments.

**(min 'n\_arg1 ...)**

RETURNS: the minimum value in the list of arguments.

**(mod 'i\_dividend 'i\_divisor)**

**(remainder 'i\_dividend 'i\_divisor)**

RETURNS: the remainder when i\_dividend is divided by i\_divisor.

NOTE: The sign of the result will have the same sign as i\_dividend.

**(\*mod 'x\_dividend 'x\_divisor)**

RETURNS: the balanced representation of x\_dividend modulo x\_divisor.

NOTE: the range of the balanced representation is  $\text{abs}(x\_divisor)/2$  to  $(\text{abs}(x\_divisor)/2) \square x\_divisor + 1$ .

**(random** [**'x\_limit**])

RETURNS: a fixnum between 0 and  $x\_limit \div 1$  if  $x\_limit$  is given. If  $x\_limit$  is not given, any fixnum, positive or negative, might be returned.

**(sqrt** 'fx\_arg)

RETURNS: the square root of  $fx\_arg$ .

## CHAPTER 4

### Special Functions

**(and** [g\_arg1 ...])

RETURNS: the value of the last argument if all arguments evaluate to a non-nil value, otherwise *and* returns nil. It returns t if there are no arguments.

NOTE: the arguments are evaluated left to right and evaluation will cease with the first nil encountered.

**(apply** 'u\_func 'l\_args)

RETURNS: the result of applying function u\_func to the arguments in the list l\_args.

NOTE: If u\_func is a lambda, then the (*length* l\_args) should equal the number of formal parameters for the u\_func. If u\_func is a lambda or macro, then l\_args is bound to the single formal parameter.

---

```
; add1 is a lambda of 1 argument
[]> (apply 'add1 '(3))
4

; we will define plus1 as a macro which will be equivalent to add1
[]> (def plus1 (macro (arg) (list 'add1 (cadr arg))))
plus1
[]> (plus1 3)
4

; now if we apply a macro we obtain the form it changes to.
[]> (apply 'plus1 '(plus1 3))
(add1 3)

; if we funcall a macro however, the result of the macro is eval'd
; before it is returned.
[]> (funcall 'plus1 '(plus1 3))
4

; for this particular macro, the car of the arg is not checked
; so that this too will work
[]> (apply 'plus1 '(foo 3))
(add1 3)
```

---

**(arg [*'x\_num*b])**

RETURNS: if *x\_num* is specified then the *x\_num*'th argument to the enclosing *lexpr*. If *x\_num* is not specified then this returns the number of arguments to the enclosing *lexpr*.

NOTE: it is an error to the interpreter if *x\_num* is given and out of range.

**(break [*g\_message*] [*'g\_pred*])**

WHERE: if *g\_message* is not given it is assumed to be the null string, and if *g\_pred* is not given it is assumed to be *t*.

RETURNS: the value of (*\*break 'g\_pred 'g\_message*)

**(\*break *'g\_pred 'g\_message*)**

RETURNS: *nil* immediately if *g\_pred* is *nil*, else the value of the next (return 'value) expression typed in at top level.

SIDE EFFECT: If the predicate, *g\_pred*, evaluates to non-null, the lisp system stops and prints out 'Break ' followed by *g\_message*. It then enters a break loop which allows one to interactively debug a program. To continue execution from a break you can use the *return* function. to return to top level or another break level, you can use *retbrk* or *reset*.

**(caseq *'g\_key*-form *l\_clause1* ...)**

WHERE: *l\_clause<sub>i</sub>* is a list of the form (*g\_comparator* [*'g\_form<sub>i</sub>* ...]). The comparators may be symbols, small fixnums, a list of small fixnums or symbols.

NOTE: The way *caseq* works is that it evaluates *g\_key*-form, yielding a value we will call the selector. Each clause is examined until the selector is found consistent with the comparator. For a symbol, or a fixnum, this means the two must be *eq*. For a list, this means that the selector must be *eq* to some element of the list.

The comparator consisting of the symbol *t* has special semantics: it matches anything, and consequently, should be the last comparator.

In any case, having chosen a clause, *caseq* evaluates each form within that clause and

RETURNS: the value of the last form. If no comparators are matched, *caseq* returns *nil*.

---

Here are two ways of defining the same function:

```

[]>(defun fate (personna)
  (caseq personna
    (cow '(jumped over the moon))
    (cat '(played nero))
    ((dish spoon) '(ran away with each other))
    (t '(lived happily ever after))))

fate
[]>(defun fate (personna)
  (cond
    ((eq personna 'cow) '(jumped over the moon))
    ((eq personna 'cat) '(played nero))
    ((memq personna '(dish spoon)) '(ran away with each other))
    (t '(lived happily ever after))))

fate

```

---

**(catch g\_exp [ls\_tag])**

WHERE: if `ls_tag` is not given, it is assumed to be `nil`.

RETURNS: the result of *(`*catch 'ls_tag g_exp`)*

NOTE: `catch` is defined as a macro.

**(\*catch 'ls\_tag g\_exp)**

WHERE: `ls_tag` is either a symbol or a list of symbols.

RETURNS: the result of evaluating `g_exp` or the value thrown during the evaluation of `g_exp`.

SIDE EFFECT: this first sets up a 'catch frame' on the lisp runtime stack. Then it begins to evaluate `g_exp`. If `g_exp` evaluates normally, its value is returned. If, however, a value is thrown during the evaluation of `g_exp` then this `*catch` will return with that value if one of these cases is true:

- (1) the tag thrown to is `ls_tag`
- (2) `ls_tag` is a list and the tag thrown to is a member of this list
- (3) `ls_tag` is `nil`.

NOTE: Errors are implemented as a special kind of throw. A catch with no tag will not catch an error but a catch whose tag is the error type will catch that type of error. See Chapter 10 for more information.

**(comment [g\_arg ...])**

RETURNS: the symbol `comment`.

NOTE: This does absolutely nothing.

**(cond [l\_clause1 ...])**

RETURNS: the last value evaluated in the first clause satisfied. If no clauses are satisfied then `nil` is returned.

NOTE: This is the basic conditional 'statement' in lisp. The clauses are processed from left to right. The first element of a clause is evaluated. If it evaluated to a non-null value then that clause is satisfied and all following elements of that clause are evaluated. The last value computed is returned as the value of the `cond`. If there is just one element in the clause then its value is returned. If the first element of a clause evaluates to `nil`, then the other elements of that clause are not evaluated and the system moves to the next clause.

**(cvttointlisp)**

SIDE EFFECT: The reader is modified to conform with the Interlisp syntax. The character `%` is made the escape character and special meanings for comma, backquote and backslash are removed. Also the reader is told to convert upper case to lower case.

**(cvttofranzlisp)**

SIDE EFFECT: FRANZ LISP's default syntax is reinstated. One would run this function after having run any of the other *cvtto-* functions. Backslash is made the escape character, super-brackets work again, and the reader distinguishes between upper and lower case.

**(cvttoaclisp)**

SIDE EFFECT: The reader is modified to conform with Maclisp syntax. The character / is made the escape character and the special meanings for backslash, left and right bracket are removed. The reader is made case-insensitive.

**(cvttoucilisp)**

SIDE EFFECT: The reader is modified to conform with UCI Lisp syntax. The character / is made the escape character, tilde is made the comment character, exclamation point takes on the unquote function normally held by comma, and backslash, comma, semicolon become normal characters. Here too, the reader is made case-insensitive.

**(debug s\_msg)**

SIDE EFFECT: Enter the Fixit package described in Chapter 15. This package allows you to examine the evaluation stack in detail. To leave the Fixit package type 'ok'.

**(debugging 'g\_arg)**

SIDE EFFECT: If *g\_arg* is non-null, Franz unlinks the transfer tables, does a (*\*reset*) to turn on evaluation monitoring and sets the all-error catcher (ER%all) to be *debug-err-handler*. If *g\_arg* is nil, all of the above changes are undone.

**(declare [g\_arg ...])**

RETURNS: nil

NOTE: this is a no-op to the evaluator. It has special meaning to the compiler (see Chapter 12).

**(def s\_name (s\_type l\_argl g\_exp1 ...))**

WHERE: *s\_type* is one of lambda, nlambda, macro or lexpr.

RETURNS: *s\_name*

SIDE EFFECT: This defines the function *s\_name* to the lisp system. If *s\_type* is nlambda or macro then the argument list *l\_argl* must contain exactly one non-nil symbol.

**(defmacro s\_name l\_arg g\_exp1 ...)****(defmacro s\_name l\_arg g\_exp1 ...)**

RETURNS: *s\_name*

SIDE EFFECT: This defines the macro *s\_name*. *defmacro* makes it easy to write macros since it makes the syntax just like *defun*. Further information on *defmacro* is in §8.3.2. *defmacro* defines compiler-only macros, or cmacros. A cmacro is stored on the property list of a symbol under the indicator **cmacro**. Thus a function can have a normal definition and a cmacro definition. For an example of the use of cmacros, see the definitions of nthcdr and nth in /usr/lib/lisp/common2.l

**(defun s\_name [s\_mtype] ls\_argl g\_exp1 ...)**

WHERE: *s\_mtype* is one of fexpr, expr, args or macro.

RETURNS: *s\_name*

SIDE EFFECT: This defines the function *s\_name*.

NOTE: this exists for Maclisp compatibility, it is just a macro which changes the defun form to the def form. An *s\_mtype* of fexpr is converted to nlambda and of expr to lambda. Macro remains the same. If *ls\_argl* is a non-nil symbol, then the type is assumed to be lexpr and *ls\_argl* is the symbol which is bound to the number of args when the function is entered.

For compatibility with the Lisp Machine Lisp, there are three types of optional parameters that can occur in *ls\_argl*: *&optional* declares that the following symbols are optional, and may or may not appear in the argument list to the function, *&rest symbol* declares that all

forms in the function call that are not accounted for by previous lambda bindings are to be assigned to *symbol*, and *&aux form1 ... formn* declares that the *formi* are either symbols, in which case they are lambda bound to **nil**, or lists, in which case the first element of the list is lambda bound to the second, evaluated element.

---

```

; def and defun here are used to define identical functions
; you can decide for yourself which is easier to use.
[]> (def append1 (lambda (lis extra) (append lis (list extra))))
append1

[]> (defun append1 (lis extra) (append lis (list extra)))
append1

; Using the & forms...
[]> (defun test (a b &optional c &aux (retval 0) &rest z)
      (if c them (msg "Optional arg present" N
                    "c is " c N))
      (msg "rest is " z N
          "retval is " retval N))
test
[]> (test 1 2 3 4)
Optional arg present
c is 3
rest is (4)
retval is 0

```

---

### (defvar s\_variable [g\_init])

RETURNS: s\_variable.

NOTE: This form is put at the top level in files, like *defun*.

SIDE EFFECT: This declares s\_variable to be special. If g\_init is present and s\_variable is unbound when the file is read in, s\_variable will be set to the value of g\_init. An advantage of '(defvar foo)' over '(declare (special foo))' is that if a file containing defvars is loaded (or fasl'ed) in during compilation, the variables mentioned in the defvar's will be declared special. The only way to have that effect with '(declare (special foo))' is to *include* the file.

### (do l\_vrbs l\_test g\_exp1 ...)

RETURNS: the last form in the cdr of l\_test evaluated, or a value explicitly given by a return evaluated within the do body.

NOTE: This is the basic iteration form for FRANZ LISP. l\_vrbs is a list of zero or more var-init-repeat forms. A var-init-repeat form looks like:

```
(s_name [g_init [g_repeat]])
```

There are three cases depending on what is present in the form. If just s\_name is present, this means that when the do is entered, s\_name is lambda-bound to nil and is never modified by the system (though the program is certainly free to modify its value). If the form is (s\_name g\_init) then the only difference is that s\_name is lambda-bound to the value of g\_init instead of nil. If g\_repeat is also present then s\_name is lambda-bound to g\_init when the loop is entered and after each pass through the do body s\_name is bound to the value of g\_repeat.

l\_test is either nil or has the form of a cond clause. If it is nil then the do body will be evaluated only once and the do will return nil. Otherwise, before the do body is evaluated the car of l\_test is evaluated and if the result is non-null, this signals an end to the looping. Then the rest of the forms in l\_test are evaluated and the value of the last one is returned as the

value of the do. If the cdr of l\_test is nil, then nil is returned -- thus this is not exactly like a cond clause.

g\_exp1 and those forms which follow constitute the do body. A do body is like a prog body and thus may have labels and one may use the functions go and return.

The sequence of evaluations is this:

- (1) the init forms are evaluated left to right and stored in temporary locations.
- (2) Simultaneously all do variables are lambda bound to the value of their init forms or nil.
- (3) If l\_test is non-null, then the car is evaluated and if it is non-null, the rest of the forms in l\_test are evaluated and the last value is returned as the value of the do.
- (4) The forms in the do body are evaluated left to right.
- (5) If l\_test is nil the do function returns with the value nil.
- (6) The repeat forms are evaluated and saved in temporary locations.
- (7) The variables with repeat forms are simultaneously bound to the values of those forms.
- (8) Go to step 3.

NOTE: there is an alternate form of do which can be used when there is only one do variable. It is described next.

---

```
; this is a simple function which numbers the elements of a list.
; It uses a do function with two local variables.
```

```
□> (defun printem (lis)
      (do ((xx lis (cdr xx))
          (i 1 (1+ i)))
          ((null xx) (patom "all done") (terpr))
          (print i)
          (patom ": ")
          (print (car xx))
          (terpr)))
```

```
printem
□> (printem '(a b c d))
1: a
2: b
3: c
4: d
all done
nil
□>
```

---

(do s\_name g\_init g\_repeat g\_test g\_exp1 ...)

NOTE: this is another, less general, form of do. It is evaluated by:

- (1) evaluating g\_init
- (2) lambda binding s\_name to value of g\_init
- (3) g\_test is evaluated and if it is not nil the do function returns with nil.
- (4) the do body is evaluated beginning at g\_exp1.
- (5) the repeat form is evaluated and stored in s\_name.
- (6) go to step 3.

RETURNS: nil

**(environment** [*l\_when1 l\_what1 l\_when2 l\_what2 ...*])

**(environment-maclisp** [*l\_when1 l\_what1 l\_when2 l\_what2 ...*])

**(environment-lmlisp** [*l\_when1 l\_what1 l\_when2 l\_what2 ...*])

WHERE: the when's are a subset of (eval compile load), and the symbols have the same meaning as they do in 'eval-when'.

The what's may be

(files file1 file2 ... fileN),

which insure that the named files are loaded. To see if file*i* is loaded, it looks for a 'version' property under file*i*'s property list. Thus to prevent multiple loading, you should put

(putprop 'myfile t 'version),

at the end of myfile.l.

Another acceptable form for a what is

(syntax type)

Where type is either maclisp, intlisp, uclisp, franzlisp.

SIDE EFFECT: *environment-maclisp* sets the environment to that which 'lispz -m' would generate.

*environment-lmlisp* sets up the lisp machine environment. This is like maclisp but it has additional macros.

For these specialized environments, only the **files** clauses are useful.

(environment-maclisp (compile eval) (files foo bar))

RETURNS: the last list of files requested.

**(err** [*'s\_value [nil]*])

RETURNS: nothing (it never returns).

SIDE EFFECT: This causes an error and if this error is caught by an *errset* then that *errset* will return *s\_value* instead of nil. If the second arg is given, then it must be nil (MAClisp compatibility).

**(error** [*'s\_message1 's\_message2*])

RETURNS: nothing (it never returns).

SIDE EFFECT: *s\_message1* and *s\_message2* are *patomed* if they are given and then *err* is called (with no arguments), which causes an error.

**(errset** *g\_expr* [*s\_flag*])

RETURNS: a list of one element, which is the value resulting from evaluating *g\_expr*. If an error occurs during the evaluation of *g\_expr*, then the locus of control will return to the *errset* which will then return nil (unless the error was caused by a call to *err*, with a non-null argument).

SIDE EFFECT: *S\_flag* is evaluated before *g\_expr* is evaluated. If *s\_flag* is not given, then it is assumed to be t. If an error occurs during the evaluation of *g\_expr*, and *s\_flag* evaluated to a non-null value, then the error message associated with the error is printed before control returns to the *errset*.

**(eval 'g\_val [x\_bind-pointer])**

RETURNS: the result of evaluating g\_val.

NOTE: The evaluator evaluates g\_val in this way:

If g\_val is a symbol, then the evaluator returns its value. If g\_val had never been assigned a value, then this causes an 'Unbound Variable' error. If x\_bind-pointer is given, then the variable is evaluated with respect to that pointer (see *evalframe* for details on bind-pointers).

If g\_val is of type value, then its value is returned. If g\_val is of any other type than list, g\_val is returned.

If g\_val is a list object then g\_val is either a function call or array reference. Let g\_car be the first element of g\_val. We continually evaluate g\_car until we end up with a symbol with a non-null function binding or a non-symbol. Call what we end up with: g\_func.

G\_func must be one of three types: list, binary or array. If it is a list then the first element of the list, which we shall call g\_func\_type, must be either lambda, nlambda, macro or lexpr. If g\_func is a binary, then its discipline, which we shall call g\_func\_type, is either lambda, nlambda, macro or a string. If g\_func is an array then this form is evaluated specially, see Chapter 9 on arrays. If g\_func is a list or binary, then g\_func\_type will determine how the arguments to this function, the cdr of g\_val, are processed. If g\_func\_type is a string, then this is a foreign function call (see §8.5 for more details).

If g\_func\_type is lambda or lexpr, the arguments are evaluated (by calling *eval* recursively) and stacked. If g\_func\_type is nlambda then the argument list is stacked. If g\_func\_type is macro then the entire form, g\_val is stacked.

Next, the formal variables are lambda bound. The formal variables are the cadr of g\_func. If g\_func\_type is nlambda, lexpr or macro, there should only be one formal variable. The values on the stack are lambda bound to the formal variables except in the case of a lexpr, where the number of actual arguments is bound to the formal variable.

After the binding is done, the function is invoked, either by jumping to the entry point in the case of a binary or by evaluating the list of forms beginning at caddr g\_func. The result of this function invocation is returned as the value of the call to *eval*.

**(evalframe 'x\_pdlpointer)**

RETURNS: an evalframe descriptor for the evaluation frame just before x\_pdlpointer. If x\_pdlpointer is nil, it returns the evaluation frame of the frame just before the current call to *evalframe*.

NOTE: An evalframe descriptor describes a call to *eval*, *apply* or *funcall*. The form of the descriptor is

*(type pdl-pointer expression bind-pointer np-index lbot-index)*

where type is 'eval' if this describes a call to *eval* or 'apply' if this is a call to *apply* or *funcall*. pdl-pointer is a number which describes this context. It can be passed to *evalframe* to obtain the next descriptor and can be passed to *freturn* to cause a return from this context. bind-pointer is the size of variable binding stack when this evaluation began. The bind-pointer can be given as a second argument to *eval* to order to evaluate variables in the same context as this evaluation. If type is 'eval' then expression will have the form *(function-name arg1 ...)*. If type is 'apply' then expression will have the form *(function-name (arg1 ...))*. np-index and lbot-index are pointers into the argument stack (also known as the *namestack* array) at the time of call. lbot-index points to the first argument, np-index points one beyond the last argument.

In order for there to be enough information for *evalframe* to return, you must call *(\*reset t)*.

EXAMPLE: *(progn (evalframe nil))*

returns *(eval 2147478600 (progn (evalframe nil)) 1 8 7)*

**(evalhook 'g\_form 'su\_evalfunc ['su\_funcallfunc])**

RETURNS: the result of evaluating *g\_form* after lambda binding 'evalhook' to *su\_evalfunc* and, if it is given, lambda binding 'funcallhook' to *su\_funcallhook*.

NOTE: As explained in §14.4, the function *eval* may pass the job of evaluating a form to a user 'hook' function when various switches are set. The hook function normally prints the form to be evaluated on the terminal and then evaluates it by calling *evalhook*. *Evalhook* does the lambda binding mentioned above and then calls *eval* to evaluate the form after setting an internal switch to tell *eval* not to call the user's hook function just this one time. This allows the evaluation process to advance one step and yet insure that further calls to *eval* will cause traps to the hook function (if *su\_evalfunc* is non-null).

In order for *evalhook* to work, (*\*rset t*) and (*status evalhook t*) must have been done previously.

**(exec s\_arg1 ...)**

RETURNS: the result of forking and executing the command named by concatenating the *s\_argi* together with spaces in between.

**(exece 's\_fname ['l\_args ['l\_envir]])**

RETURNS: the error code from the system if it was unable to execute the command *s\_fname* with arguments *l\_args* and with the environment set up as specified in *l\_envir*. If this function is successful, it will not return, instead the lisp system will be overlaid by the new command.

**(freturn 'x\_pdl-pointer 'g\_retval)**

RETURNS: *g\_retval* from the context given by *x\_pdl-pointer*.

NOTE: A pdl-pointer denotes a certain expression currently being evaluated. The pdl-pointer for a given expression can be obtained from *evalframe*.

**(frexp 'f\_arg)**

RETURNS: a list cell (*exponent . mantissa*) which represents the given flonum

NOTE: The exponent will be a fixnum, the mantissa a 56 bit bignum. If you think of the the binary point occurring right after the high order bit of mantissa, then  $f\_arg = 2^{\text{exponent}} * \text{mantissa}$ .

**(funcall 'u\_func ['g\_arg1 ...])**

RETURNS: the value of applying function *u\_func* to the arguments *g\_argi* and then evaluating that result if *u\_func* is a macro.

NOTE: If *u\_func* is a macro or *nlambda* then there should be only one *g\_arg*. *funcall* is the function which the evaluator uses to evaluate lists. If *foo* is a lambda or *lexpr* or array, then (*funcall 'foo 'a 'b 'c*) is equivalent to (*foo 'a 'b 'c*). If *foo* is a *nlambda* then (*funcall 'foo '(a b c)*) is equivalent to (*foo a b c*). Finally, if *foo* is a macro then (*funcall 'foo '(foo a b c)*) is equivalent to (*foo a b c*).

**(funcallhook 'l\_form 'su\_funcallfunc ['su\_evalfunc])**

RETURNS: the result of *funcalling* the (*car l\_form*) on the already evaluated arguments in the (*cdr l\_form*) after lambda binding 'funcallhook' to su\_funcallfunc and, if it is given, lambda binding 'evalhook' to su\_evalhook.

NOTE: This function is designed to continue the evaluation process with as little work as possible after a funcallhook trap has occurred. It is for this reason that the form of l\_form is unorthodox: its *car* is the name of the function to call and its *cdr* are a list of arguments to stack (without evaluating again) before calling the given function. After stacking the arguments but before calling *funcall* an internal switch is set to prevent *funcall* from passing the job of funcalling to su\_funcallfunc. If *funcall* is called recursively in funcalling l\_form and if su\_funcallfunc is non-null, then the arguments to *funcall* will actually be given to su\_funcallfunc (a lexpr) to be funcalled.

In order for *evalhook* to work, (*\*rset t*) and (*sstatus evalhook t*) must have been done previously. A more detailed description of *evalhook* and *funcallhook* is given in Chapter 14.

**(function u\_func)**

RETURNS: the function binding of u\_func if it is a symbol with a function binding otherwise u\_func is returned.

**(getdisc 'y\_func)**

RETURNS: the discipline of the machine coded function (either lambda, nlambda or macro).

**(go g\_labexp)**

WHERE: g\_labexp is either a symbol or an expression.

SIDE EFFECT: If g\_labexp is an expression, that expression is evaluated and should result in a symbol. The locus of control moves to just following the symbol g\_labexp in the current prog or do body.

NOTE: this is only valid in the context of a prog or do body. The interpreter and compiler will allow non-local *go*'s although the compiler won't allow a *go* to leave a function body. The compiler will not allow g\_labexp to be an expression.

**(if 'g\_a 'g\_b)****(if 'g\_a 'g\_b 'g\_c ...)****(if 'g\_a then 'g\_b [...] [elseif 'g\_c then 'g\_d ...] [else 'g\_e [...]])****(if 'g\_a then 'g\_b [...] [elseif 'g\_c thenret] [else 'g\_d [...]])**

NOTE: The various forms of *if* are intended to be a more readable conditional statement, to be used in place of *cond*. There are two varieties of *if*, with keywords, and without. The keyword-less variety is inherited from common Maclisp usage. A keyword-less, two argument *if* is equivalent to a one-clause *cond*, i.e. (*cond* (a b)). Any other keyword-less *if* must have at least three arguments. The first two arguments are the first clause of the equivalent *cond*, and all remaining arguments are shoved into a second clause beginning with **t**. Thus, the second form of *if* is equivalent to

(*cond* (a b) (t c ...)).

The keyword variety has the following grouping of arguments: a predicate, a then-clause, and optional else-clause. The predicate is evaluated, and if the result is non-nil, the then-clause will be performed, in the sense described below. Otherwise, (i.e. the result of the predicate evaluation was precisely nil), the else-clause will be performed.

Then-clauses will either consist entirely of the single keyword **thenret**, or will start with the keyword **then**, and be followed by at least one general expression. (These general expressions must not be one of the keywords.) To actuate a **thenret** means to cease further evaluation of the *if*, and to return the value of the predicate just calculated. The performance of the longer clause means to evaluate each general expression in turn, and then return the last value

calculated.

The else-clause may begin with the keyword **else** and be followed by at least one general expression. The rendition of this clause is just like that of a then-clause. An else-clause may begin alternatively with the keyword **elseif**, and be followed (recursively) by a predicate, then-clause, and optional else-clause. Evaluation of this clause, is just evaluation of an *if*-form, with the same predicate, then- and else-clauses.

**(I-throw-err 'l\_token)**

WHERE: l\_token is the *cdr* of the value returned from a *\*catch* with the tag ER%unwind-protect.

RETURNS: nothing (never returns in the current context)

SIDE EFFECT: The error or throw denoted by l\_token is continued.

NOTE: This function is used to implement *unwind-protect* which allows the processing of a transfer of control though a certain context to be interrupted, a user function to be executed and then the transfer of control to continue. The form of l\_token is either

(*t tag value*) for a throw or

(*nil type message valret contuab uniqueid [arg ...]*) for an error.

This function is not to be used for implementing throws or errors and is only documented here for completeness.

**(let l\_args g\_exp1 ... g\_exprn)**

RETURNS: the result of evaluating g\_exprn within the bindings given by l\_args.

NOTE: l\_args is either nil (in which case *let* is just like *progn*) or it is a list of binding objects. A binding object is a list (*symbol expression*). When a *let* is entered, all of the expressions are evaluated and then simultaneously lambda-bound to the corresponding symbols. In effect, a *let* expression is just like a lambda expression except the symbols and their initial values are next to each other, making the expression easier to understand. There are some added features to the *let* expression: A binding object can just be a symbol, in which case the expression corresponding to that symbol is 'nil'. If a binding object is a list and the first element of that list is another list, then that list is assumed to be a binding template and *let* will do a *desetaq* on it.

**(let\* l\_args g\_exp1 ... g\_exprn)**

RETURNS: the result of evaluating g\_exprn within the bindings given by l\_args.

NOTE: This is identical to *let* except the expressions in the binding list l\_args are evaluated and bound sequentially instead of in parallel.

**(lexpr-funcall 'g\_function ['g\_arg1 ...] 'l\_argn)**

NOTE: This is a cross between *funcall* and *apply*. The last argument, must be a list (possibly empty). The element of list arg are stack and then the function is funcalled.

EXAMPLE: (lexpr-funcall 'list 'a '(b c d)) is the same as  
(funcall 'list 'a 'b 'c 'd)

**(listify 'x\_count)**

RETURNS: a list of x\_count of the arguments to the current function (which must be a lexpr).

NOTE: normally arguments 1 through x\_count are returned. If x\_count is negative then a list of last abs(x\_count) arguments are returned.

**(map 'u\_func 'l\_arg1 ...)**

RETURNS: l\_arg1

NOTE: The function u\_func is applied to successive sublists of the l\_argi. All sublists should have the same length.

**(mapc 'u\_func 'l\_arg1 ...)**

RETURNS: l\_arg1.

NOTE: The function u\_func is applied to successive elements of the argument lists. All of the lists should have the same length.

**(mapcan 'u\_func 'l\_arg1 ...)**

RETURNS: nconc applied to the results of the functional evaluations.

NOTE: The function u\_func is applied to successive elements of the argument lists. All sublists should have the same length.

**(mapcar 'u\_func 'l\_arg1 ...)**

RETURNS: a list of the values returned from the functional application.

NOTE: the function u\_func is applied to successive elements of the argument lists. All sublists should have the same length.

**(mapcon 'u\_func 'l\_arg1 ...)**

RETURNS: nconc applied to the results of the functional evaluation.

NOTE: the function u\_func is applied to successive sublists of the argument lists. All sublists should have the same length.

**(maplist 'u\_func 'l\_arg1 ...)**

RETURNS: a list of the results of the functional evaluations.

NOTE: the function u\_func is applied to successive sublists of the arguments lists. All sublists should have the same length.

Readers may find the following summary table useful in remembering the differences between the six mapping functions:

Argument to func-tional is	Value returned is		
	l_arg1	list of results	nconc of results
elements of list	mapc	mapcar	mapcan
sublists	map	maplist	mapcon

**(mfunction t\_entry 's\_disc)**

RETURNS: a lisp object of type binary composed of t\_entry and s\_disc.

NOTE: t\_entry is a pointer to the machine code for a function, and s\_disc is the discipline (e.g. lambda).

**(oblist)**

RETURNS: a list of all symbols on the oblist.

**(or [g\_arg1 ...])**

RETURNS: the value of the first non-null argument or nil if all arguments evaluate to nil.

NOTE: Evaluation proceeds left to right and stops as soon as one of the arguments evaluates to a non-null value.

**(prog l\_vrbls g\_exp1 ...)**

RETURNS: the value explicitly given in a return form or else nil if no return is done by the time the last g\_exp<sub>i</sub> is evaluated.

NOTE: the local variables are lambda-bound to nil, then the g\_exp<sub>i</sub> are evaluated from left to right. This is a prog body (obviously) and this means that any symbols seen are not evaluated, but are treated as labels. This also means that return's and go's are allowed.

**(prog1 'g\_exp1 ['g\_exp2 ...])**

RETURNS: g\_exp1

**(prog2 'g\_exp1 'g\_exp2 ['g\_exp3 ...])**

RETURNS: g\_exp2

NOTE: the forms are evaluated from left to right and the value of g\_exp2 is returned.

**(progn 'g\_exp1 ['g\_exp2 ...])**

RETURNS: the last g\_exp<sub>i</sub>.

**(progv 'l\_locv 'l\_initv g\_exp1 ...)**

WHERE: l\_locv is a list of symbols and l\_initv is a list of expressions.

RETURNS: the value of the last g\_exp<sub>i</sub> evaluated.

NOTE: The expressions in l\_initv are evaluated from left to right and then lambda-bound to the symbols in l\_locv. If there are too few expressions in l\_initv then the missing values are assumed to be nil. If there are too many expressions in l\_initv then the extra ones are ignored (although they are evaluated). Then the g\_exp<sub>i</sub> are evaluated left to right. The body of a prog is like the body of a progn, it is *not* a prog body. (C.f. *let*)

**(purcopy 'g\_exp)**

RETURNS: a copy of g\_exp with new pure cells allocated wherever possible.

NOTE: pure space is never swept up by the garbage collector, so this should only be done on expressions which are not likely to become garbage in the future. In certain cases, data objects in pure space become read-only after a *dumplisp* and then an attempt to modify the object will result in an illegal memory reference.

**(purep 'g\_exp)**

RETURNS: *t* iff the object *g\_exp* is in pure space.

**(putd 's\_name 'u\_func)**

RETURNS: *u\_func*

SIDE EFFECT: this sets the function binding of symbol *s\_name* to *u\_func*.

**(return ['g\_val])**

RETURNS: *g\_val* (or *nil* if *g\_val* is not present) from the enclosing *prog* or *do* body.

NOTE: this form is only valid in the context of a *prog* or *do* body.

**(selectq 'g\_key-form [l\_clause1 ...])**

NOTE: This function is just like *caseq* (see above), except that the symbol **otherwise** has the same semantics as the symbol **t**, when used as a comparator.

**(setarg 'x\_argnum 'g\_val)**

WHERE: *x\_argnum* is greater than zero and less than or equal to the number of arguments to the *lexpr*.

RETURNS: *g\_val*

SIDE EFFECT: the *lexpr*'s *x\_argnum*'th argument is set to *g\_val*.

NOTE: this can only be used within the body of a *lexpr*.

**(throw 'g\_val [s\_tag])**

WHERE: if *s\_tag* is not given, it is assumed to be *nil*.

RETURNS: the value of *(\*throw 's\_tag 'g\_val)*.

**(\*throw 's\_tag 'g\_val)**

RETURNS: *g\_val* from the first enclosing *catch* with the tag *s\_tag* or with no tag at all.

NOTE: this is used in conjunction with *\*catch* to cause a clean jump to an enclosing context.

**(unwind-protect g\_protected [g\_cleanup1 ...])**

RETURNS: the result of evaluating *g\_protected*.

NOTE: Normally *g\_protected* is evaluated and its value remembered, then the *g\_cleanup<sub>i</sub>* are evaluated and finally the saved value of *g\_protected* is returned. If something should happen when evaluating *g\_protected* which causes control to pass through *g\_protected* and thus through the call to the *unwind-protect*, then the *g\_cleanup<sub>i</sub>* will still be evaluated. This is useful if *g\_protected* does something sensitive which must be cleaned up whether or not *g\_protected* completes.

## CHAPTER 5

### Input/Output

The following functions are used to read from and write to external devices (e.g. files) and programs (through pipes). All I/O goes through the lisp data type called the port. A port may be open for either reading or writing, but usually not both simultaneously (see *fileopen*). There are only a limited number of ports (20) and they will not be reclaimed unless they are *closed*. All ports are reclaimed by a *resetio* call, but this drastic step won't be necessary if the program closes what it uses.

If a port argument is not supplied to a function which requires one, or if a bad port argument (such as nil) is given, then FRANZ LISP will use the default port according to this scheme: If input is being done then the default port is the value of the symbol **piport** and if output is being done then the default port is the value of the symbol **poport**. Furthermore, if the value of piport or poport is not a valid port, then the standard input or standard output will be used, respectively.

The standard input and standard output are usually the keyboard and terminal display unless your job is running in the background and its input or output is connected to a pipe. All output which goes to the standard output will also go to the port **ptport** if it is a valid port. Output destined for the standard output will not reach the standard output if the symbol **^w** is non nil (although it will still go to **ptport** if **ptport** is a valid port).

Some of the functions listed below reference files directly. FRANZ LISP has borrowed a convenient shorthand notation from */bin/csh*, concerning naming files. If a file name begins with **~** (tilde), and the symbol **tilde-expansion**

is bound to something other than nil, then FRANZ LISP expands the file name. It takes the string of characters between the leading tilde, and the first slash as a user-name. Then, that initial segment of the filename is replaced by the home directory of the user. The null username is taken to be the current user.

FRANZ LISP keeps a cache of user home directory information, to minimize searching the password file. Tilde-expansion is performed in the following functions: *cfasl*, *chdir*, *fasl*, *ffasl*, *fileopen*, *infile*, *load*, *outfile*, *probef*, *sys:access*, *sys:unlink*.

**(cfasl 'st\_file 'st\_entry 'st\_funcname ['st\_disc ['st\_library]])**

RETURNS: t

SIDE EFFECT: This is used to load in a foreign function (see §8.4). The object file *st\_file* is loaded into the lisp system. *St\_entry* should be an entry point in the file just loaded. The function binding of the symbol *s\_funcname* will be set to point to *st\_entry*, so that when the lisp function *s\_funcname* is called, *st\_entry* will be run. *st\_disc* is the discipline to be given to *s\_funcname*. *st\_disc* defaults to "subroutine" if it is not given or if it is given as nil. If *st\_library* is non-null, then after *st\_file* is loaded, the libraries given in *st\_library* will be searched to resolve external references. The form of *st\_library* should be something like "-lm". The C library (" -lc ") is always searched so when loading in a C file you probably won't need to specify a library. For Fortran files, you should specify "-lf77" and if you are doing any I/O, the library entry should be "-lf77 -lf77". For Pascal files "-lpc" is required.

NOTE: This function may be used to load the output of the assembler, C compiler, Fortran compiler, and Pascal compiler but NOT the lisp compiler (use *fasl* for that). If a file has more than one entry point, then use *getaddress* to locate and setup other foreign functions.

It is an error to load in a file which has a global entry point of the same name as a global entry point in the running lisp. As soon as you load in a file with *cfasl*, its global entry points

become part of the lisp's entry points. Thus you cannot *cfasl* in the same file twice unless you use *removeaddress* to change certain global entry points to local entry points.

**(close 'p\_port)**

RETURNS: t

SIDE EFFECT: the specified port is drained and closed, releasing the port.

NOTE: The standard defaults are not used in this case since you probably never want to close the standard output or standard input.

**(cprintf 'st\_format 'xfst\_val ['p\_port])**

RETURNS: xfst\_val

SIDE EFFECT: The UNIX formatted output function printf is called with arguments st\_format and xfst\_val. If xfst\_val is a symbol then its print name is passed to printf. The format string may contain characters which are just printed literally and it may contain special formatting commands preceded by a percent sign. The complete set of formatting characters is described in the UNIX manual. Some useful ones are %d for printing a fixnum in decimal, %f or %e for printing a flonum, and %s for printing a character string (or print name of a symbol).

EXAMPLE: (*cprintf* "Pi equals %f" 3.14159) prints 'Pi equals 3.14159'

**(drain ['p\_port])**

RETURNS: nil

SIDE EFFECT: If this is an output port then the characters in the output buffer are all sent to the device. If this is an input port then all pending characters are flushed. The default port for this function is the default output port.

**(ex [s\_filename])****(vi [s\_filename])****(exl [s\_filename])****(vil [s\_filename])**

RETURNS: nil

SIDE EFFECT: The lisp system starts up an editor on the file named as the argument. It will try appending .l to the file if it can't find it. The functions *exl* and *vil* will load the file after you finish editing it. These functions will also remember the name of the file so that on subsequent invocations, you don't need to provide the argument.

NOTE: These functions do not evaluate their argument.

**(fasl 'st\_name ['st\_mapf ['g\_warn]])**

WHERE: st\_mapf and g\_warn default to nil.

RETURNS: t if the function succeeded, nil otherwise.

SIDE EFFECT: this function is designed to load in an object file generated by the lisp compiler Liszt. File names for object files usually end in '.o', so *fasl* will append '.o' to st\_name (if it is not already present). If st\_mapf is non nil, then it is the name of the map file to create. *Fasl* writes in the map file the names and addresses of the functions it loads and defines. Normally the map file is created (i.e. truncated if it exists), but if (*sstatus appendmap t*) is done then the map file will be appended. If g\_warn is non nil and if a function is loaded from the file which is already defined, then a warning message will be printed.

NOTE: *fasl* only looks in the current directory for the file to load. The function *load* looks through a user-supplied search path and will call *fasl* if it finds a file with the same root name and a '.o' extension. In most cases the user would be better off using the function *load* rather than

calling *fasl* directly.

**(ffasl** 'st\_file' 'st\_entry' 'st\_funcname' ['st\_discipline' ['st\_library]])

RETURNS: the binary object created.

SIDE EFFECT: the Fortran object file *st\_file* is loaded into the lisp system. *St\_entry* should be an entry point in the file just loaded. A binary object will be created and its entry field will be set to point to *st\_entry*. The discipline field of the binary will be set to *st\_discipline* or "subroutine" by default. If *st\_library* is present and non-null, then after *st\_file* is loaded, the libraries given in *st\_library* will be searched to resolve external references. The form of *st\_library* should be something like "-IS -ltermcap". In any case, the standard Fortran libraries will be searched also to resolve external references.

NOTE: in F77 on Unix, the entry point for the fortran function *foo* is named *'\_foo\_'*.

**(filepos** 'p\_port' ['x\_pos'])

RETURNS: the current position in the file if *x\_pos* is not given or else *x\_pos* if *x\_pos* is given.

SIDE EFFECT: If *x\_pos* is given, the next byte to be read or written to the port will be at position *x\_pos*.

**(filestat** 'st\_filename')

RETURNS: a vector containing various numbers which the UNIX operating system assigns to files. if the file doesn't exist, an error is invoked. Use *probef* to determine if the file exists.

NOTE: The individual entries can be accessed by mnemonic functions of the form *filestat:field*, where *field* may be any of *atime*, *ctime*, *dev*, *gid*, *ino*, *mode*, *mtime*, *nlink*, *rdev*, *size*, *type*, *uid*. See the UNIX programmers manual for a more detailed description of these quantities.

**(flatc** 'g\_form' ['x\_max'])

RETURNS: the number of characters required to print *g\_form* using *patom*. If *x\_max* is given and if *flatc* determines that it will return a value greater than *x\_max*, then it gives up and returns the current value it has computed. This is useful if you just want to see if an expression is larger than a certain size.

**(flatsize** 'g\_form' ['x\_max'])

RETURNS: the number of characters required to print *g\_form* using *print*. The meaning of *x\_max* is the same as for *flatc*.

NOTE: Currently this just *explode*'s *g\_form* and checks its length.

**(fileopen** 'st\_filename' 'st\_mode')

RETURNS: a port for reading or writing (depending on *st\_mode*) the file *st\_name*.

SIDE EFFECT: the given file is opened (or created if opened for writing and it doesn't yet exist).

NOTE: this function call provides a direct interface to the operating system's *fopen* function. The mode may be more than just "r" for read, "w" for write or "a" for append. The modes "r+", "w+" and "a+" permit both reading and writing on a port provided that *fseek* is done between changes in direction. See the UNIX manual description of *fopen* for more details. This routine does not look through a search path for a given file.

**(fseek 'p\_port 'x\_offset 'x\_flag)**

RETURNS: the position in the file after the function is performed.

SIDE EFFECT: this function positions the read/write pointer before a certain byte in the file. If `x_flag` is 0 then the pointer is set to `x_offset` bytes from the beginning of the file. If `x_flag` is 1 then the pointer is set to `x_offset` bytes from the current location in the file. If `x_flag` is 2 then the pointer is set to `x_offset` bytes from the end of the file.

**(infile 's\_filename)**

RETURNS: a port ready to read `s_filename`.

SIDE EFFECT: this tries to open `s_filename` and if it cannot or if there are no ports available it gives an error message.

NOTE: to allow your program to continue on a file-not-found error, you can use something like:

```
(cond ((null (setq myport (car (errset (infile name) nil))))
      (patom "couldn't open the file")))
```

which will set `myport` to the port to read from if the file exists or will print a message if it couldn't open it and also set `myport` to `nil`. To simply determine if a file exists, use *probef*.

**(load 's\_filename ['st\_map ['g\_warn]])**

RETURNS: `t`

NOTE: The function of *load* has changed since previous releases of FRANZ LISP and the following description should be read carefully.

SIDE EFFECT: *load* now serves the function of both *fasl* and the old *load*. *Load* will search a user defined search path for a lisp source or object file with the filename `s_filename` (with the extension `.l` or `.o` added as appropriate). The search path which *load* uses is the value of *(status load-search-path)*. The default is `(.l /usr/lib/lisp)` which means look in the current directory first and then `/usr/lib/lisp`. The file which *load* looks for depends on the last two characters of `s_filename`. If `s_filename` ends with  `".l"` then *load* will only look for a file name `s_filename` and will assume that this is a FRANZ LISP source file. If `s_filename` ends with  `".o"` then *load* will only look for a file named `s_filename` and will assume that this is a FRANZ LISP object file to be *fasted* in. Otherwise, *load* will first look for `s_filename.o`, then `s_filename.l` and finally `s_filename` itself. If it finds `s_filename.o` it will assume that this is an object file, otherwise it will assume that it is a source file. An object file is loaded using *fasl* and a source file is loaded by reading and evaluating each form in the file. The optional arguments `st_map` and `g_warn` are passed to *fasl* should *fasl* be called.

NOTE: *load* requires a port to open the file `s_filename`. It then lambda binds the symbol `piport` to this port and reads and evaluates the forms.

**(makereadtable ['s\_flag])**

WHERE: if `s_flag` is not present it is assumed to be `nil`.

RETURNS: a readtable equal to the original readtable if `s_flag` is non-null, or else equal to the current readtable. See chapter 7 for a description of readtables and their uses.

**(msg** [*l\_option ...*] [*'g\_msg ...*])

NOTE: This function is intended for printing short messages. Any of the arguments or options presented can be used any number of times, in any order. The messages themselves (*g\_msg*) are evaluated, and then they are transmitted to *patom*. Typically, they are strings, which evaluate to themselves. The options are interpreted specially:

---

*msg Option Summary*

<i>(P p_portname)</i>	causes subsequent output to go to the port <i>p_portname</i> (port should be opened previously)
<i>B</i>	print a single blank.
<i>(B 'n_b)</i>	evaluate <i>n_b</i> and print that many blanks.
<i>N</i>	print a single by calling <i>terpr</i> .
<i>(N 'n_n)</i>	evaluate <i>n_n</i> and transmit that many newlines to the stream.
<i>D</i>	<i>drain</i> the current port.

---

**(nwrite** [*'p\_port*])

RETURNS: the number of characters in the buffer of the given port but not yet written out to the file or device. The buffer is flushed automatically when filled, or when *terpr* is called.

**(outfile** *'s\_filename* [*'st\_type*])

RETURNS: a port or nil

SIDE EFFECT: this opens a port to write *s\_filename*. If *st\_type* is given and if it is a symbol or string whose name begins with 'a', then the file will be opened in append mode, that is the current contents will not be lost and the next data will be written at the end of the file. Otherwise, the file opened is truncated by *outfile* if it existed beforehand. If there are no free ports, *outfile* returns nil. If one cannot write on *s\_filename*, an error is signalled.

**(patom** *'g\_exp* [*'p\_port*])

RETURNS: *g\_exp*

SIDE EFFECT: *g\_exp* is printed to the given port or the default port. If *g\_exp* is a symbol or string, the print name is printed without any escape characters around special characters in the print name. If *g\_exp* is a list then *patom* has the same effect as *print*.

**(pntlen 'xfs\_arg)**

RETURNS: the number of characters needed to print xfs\_arg.

**(portp 'g\_arg)**

RETURNS: t iff g\_arg is a port.

**(pp [l\_option] s\_name1 ...)**

RETURNS: t

SIDE EFFECT: If s\_name<sub>i</sub> has a function binding, it is pretty-printed, otherwise if s\_name<sub>i</sub> has a value then that is pretty-printed. Normally the output of the pretty-printer goes to the standard output port poport. The options allow you to redirect it.

---

*PP Option Summary*

<i>(F s_filename)</i>	direct future printing to s_filename
<i>(P p_portname)</i>	causes output to go to the port p_portname (port should be opened previously)
<i>(E g_expression)</i>	evaluate g_expression and don't print

---

**(princ 'g\_arg ['p\_port])**

EQUIVALENT TO: patom.

**(print 'g\_arg ['p\_port])**

RETURNS: nil

SIDE EFFECT: prints g\_arg on the port p\_port or the default port.

**(probef 'st\_file)**

RETURNS: t iff the file st\_file exists.

NOTE: Just because it exists doesn't mean you can read it.

**(pp-form 'g\_form ['p\_port])**

RETURNS: t

SIDE EFFECT: g\_form is pretty-printed to the port p\_port (or poport if p\_port is not given). This is the function which *pp* uses. *pp-form* does not look for function definitions or values of variables, it just prints out the form it is given.

NOTE: This is useful as a top-level-printer, c.f. *top-level* in Chapter 6.

**(ratom** [*'p\_port* [*'g\_eof*]])

RETURNS: the next atom read from the given or default port. On end of file, *g\_eof* (default nil) is returned.

**(read** [*'p\_port* [*'g\_eof*]])

RETURNS: the next lisp expression read from the given or default port. On end of file, *g\_eof* (default nil) is returned.

NOTE: An error will occur if the reader is given an ill formed expression. The most common error is too many right parentheses (note that this is not considered an error in Maclisp).

**(readc** [*'p\_port* [*'g\_eof*]])

RETURNS: the next character read from the given or default port. On end of file, *g\_eof* (default nil) is returned.

**(readlist** *'l\_arg*)

RETURNS: the lisp expression read from the list of characters in *l\_arg*.

**(removeaddress** *'s\_name1* [*'s\_name2 ...*])

RETURNS: nil

SIDE EFFECT: the entries for the *s\_name<sub>i</sub>* in the Lisp symbol table are removed. This is useful if you wish to *cfasl* or *ffasl* in a file twice, since it is illegal for a symbol in the file you are loading to already exist in the lisp symbol table.

**(resetio)**

RETURNS: nil

SIDE EFFECT: all ports except the standard input, output and error are closed.

**(setsyntax** *'s\_symbol* *'s\_synclass* [*'ls\_func*])

RETURNS: t

SIDE EFFECT: this sets the code for *s\_symbol* to *sx\_code* in the current readtable. If *s\_synclass* is *macro* or *splicing* then *ls\_func* is the associated function. See Chapter 7 on the reader for more details.

**(sload** *'s\_file*)

SIDE EFFECT: the file *s\_file* (in the current directory) is opened for reading and each form is read, printed and evaluated. If the form is recognizable as a function definition, only its name will be printed, otherwise the whole form is printed.

NOTE: This function is useful when a file refuses to load because of a syntax error and you would like to narrow down where the error is.

**(tab** *'x\_col* [*'p\_port*])

SIDE EFFECT: enough spaces are printed to put the cursor on column *x\_col*. If the cursor is beyond *x\_col* to start with, a *terpr* is done first.

**(terpr** [*'p\_port*])

RETURNS: nil

SIDE EFFECT: a terminate line character sequence is sent to the given port or the default port. This will also drain the port.

**(terpri** [*'p\_port*])EQUIVALENT TO: `terpr`.**(tilde-expand** *'st\_filename*)

RETURNS: a symbol whose pname is the tilde-expansion of the argument, (as discussed at the beginning of this chapter). If the argument does not begin with a tilde, the argument itself is returned.

**(tyi** [*'p\_port*])

RETURNS: the fixnum representation of the next character read. On end of file, -1 is returned.

**(tyipeek** [*'p\_port*])

RETURNS: the fixnum representation of the next character to be read.

NOTE: This does not actually read the character, it just peeks at it.

**(tyo** *'x\_char* [*'p\_port*])RETURNS: *x\_char*.SIDE EFFECT: the character whose fixnum representation is *x\_code*, is printed as *a* on the given output port or the default output port.**(untyi** *'x\_char* [*'p\_port*])SIDE EFFECT: *x\_char* is put back in the input buffer so a subsequent *tyi* or *read* will read it first.

NOTE: a maximum of one character may be put back.

**(username-to-dir** *'st\_name*)

RETURNS: the home directory of the given user. The result is stored, to avoid unnecessarily searching the password file.

**(zapline)**

RETURNS: nil

SIDE EFFECT: all characters up to and including the line termination character are read and discarded from the last port used for input.

NOTE: this is used as the macro function for the semicolon character when it acts as a comment character.

## CHAPTER 6

### System Functions

This chapter describes the functions used to interact with internal components of the Lisp system and operating system.

#### (**allocate** 's\_type 'x\_pages)

WHERE: s\_type is one of the FRANZ LISP data types described in §1.3.

RETURNS: x\_pages.

SIDE EFFECT: FRANZ LISP attempts to allocate x\_pages of type s\_type. If there aren't x\_pages of memory left, no space will be allocated and an error will occur. The storage that is allocated is not given to the caller, instead it is added to the free storage list of s\_type. The functions *segment* and *small-segment* allocate blocks of storage and return it to the caller.

#### (**argv** 'x\_argnumb)

RETURNS: a symbol whose pname is the x\_argnumbth argument (starting at 0) on the command line which invoked the current lisp.

NOTE: if x\_argnumb is less than zero, a fixnum whose value is the number of arguments on the command line is returned. (*argv 0*) returns the name of the lisp you are running.

#### (**baktrace**)

RETURNS: nil

SIDE EFFECT: the lisp runtime stack is examined and the name of (most) of the functions currently in execution are printed, most active first.

NOTE: this will occasionally miss the names of compiled lisp functions due to incomplete information on the stack. If you are tracing compiled code, then *baktrace* won't be able to interpret the stack unless (*sstatus translink nil*) was done. See the function *showstack* for another way of printing the lisp runtime stack. This misspelling is from Maclisp.

#### (**chdir** 's\_path)

RETURNS: t iff the system call succeeds.

SIDE EFFECT: the current directory set to s\_path. Among other things, this will affect the default location where the input/output functions look for and create files.

NOTE: *chdir* follows the standard UNIX conventions, if s\_path does not begin with a slash, the default path is changed to the current path with s\_path appended. *Chdir* employs tilde-expansion (discussed in Chapter 5).

**(command-line-args)**

RETURNS: a list of the arguments typed on the command line, either to the lisp interpreter, or saved lisp dump, or application compiled with the autorun option (liszt -r).

**(deref 'x\_addr)**

RETURNS: The contents of x\_addr, when thought of as a longword memory location.

NOTE: This may be useful in constructing arguments to C functions out of 'dangerous' areas of memory.

**(dumplisp s\_name)**

RETURNS: nil

SIDE EFFECT: the current lisp is dumped to the named file. When s\_name is executed, you will be in a lisp in the same state as when the dumplisp was done.

NOTE: dumplisp will fail if one tries to write over the current running file. UNIX does not allow you to modify the file you are running.

**(eval-when l\_time g\_exp1 ...)**

SIDE EFFECT: l\_time may contain any combination of the symbols *load*, *eval*, and *compile*. The effects of load and compile is discussed in §12.3.2.1 compiler. If eval is present however, this simply means that the expressions g\_exp1 and so on are evaluated from left to right. If eval is not present, the forms are not evaluated.

**(exit ['x\_code])**

RETURNS: nothing (it never returns).

SIDE EFFECT: the lisp system dies with exit code x\_code or 0 if x\_code is not specified.

**(fake 'x\_addr)**

RETURNS: the lisp object at address x\_addr.

NOTE: This is intended to be used by people debugging the lisp system.

**(fork)**

RETURNS: nil to the child process and the process number of the child to the parent.

SIDE EFFECT: A copy of the current lisp system is made in memory and both lisp systems now begin to run. This function can be used interactively to temporarily save the state of Lisp (as shown below), but you must be careful that only one of the lisp's interacts with the terminal after the fork. The *wait* function is useful for this.

---

```

[]> (setq foo 'bar)           ;; set a variable
bar
[]> (cond ((fork)(wait)))     ;; duplicate the lisp system and
nil                          ;; make the parent wait
[]> foo                       ;; check the value of the variable
bar
[]> (setq foo 'baz)          ;; give it a new value
baz
[]> foo                       ;; make sure it worked
baz
[]> (exit)                   ;; exit the child
(5274 . 0)                   ;; the wait function returns this
[]> foo                       ;; we check to make sure parent was
bar                          ;; not modified.

```

---

**(gc)**

RETURNS: nil

SIDE EFFECT: this causes a garbage collection.

NOTE: The function *gcafter* is not called automatically after this function finishes. Normally the user doesn't have to call *gc* since garbage collection occurs automatically whenever internal free lists are exhausted.

**(gcafter s\_type)**

WHERE: *s\_type* is one of the FRANZ LISP data types listed in §1.3.

NOTE: this function is called by the garbage collector after a garbage collection which was caused by running out of data type *s\_type*. This function should determine if more space need be allocated and if so should allocate it. There is a default *gcafter* function but users who want control over space allocation can define their own -- but note that it must be an *nlambda*.

**(getenv 's\_name)**

RETURNS: a symbol whose *pname* is the value of *s\_name* in the current UNIX environment. If *s\_name* doesn't exist in the current environment, a symbol with a null *pname* is returned.

**(hashtabstat)**

RETURNS: a list of fixnums representing the number of symbols in each bucket of the oblist.

NOTE: the oblist is stored a hash table of buckets. Ideally there would be the same number of symbols in each bucket.

**(help [sx\_arg])**

SIDE EFFECT: If *sx\_arg* is a symbol then the portion of this manual beginning with the description of *sx\_arg* is printed on the terminal. If *sx\_arg* is a fixnum or the name of one of the appendicies, that chapter or appendix is printed on the terminal. If no argument is provided, *help* prints the options that it recognizes. The program 'more' is used to print the manual on the terminal; it will stop after each page and will continue after the space key is pressed.

**(include s\_filename)**

RETURNS: nil

SIDE EFFECT: The given filename is *loaded* into the lisp.

NOTE: this is similar to load except the argument is not evaluated. Include means something special to the compiler.

**(include-if 'g\_predicate s\_filename)**

RETURNS: nil

SIDE EFFECT: This has the same effect as include, but is only actuated if the predicate is non-nil.

**(includef 's\_filename)**

RETURNS: nil

SIDE EFFECT: this is the same as *include* except the argument is evaluated.

**(includef-if 'g\_predicate s\_filename)**

RETURNS: nil

SIDE EFFECT: This has the same effect as includef, but is only actuated if the predicate is non-nil.

**(maknum 'g\_arg)**

RETURNS: the address of its argument converted into a fixnum.

**(monitor ['xs\_maxaddr])**

RETURNS: t

SIDE EFFECT: If xs\_maxaddr is t then profiling of the entire lisp system is begun. If xs\_maxaddr is a fixnum then profiling is done only up to address xs\_maxaddr. If xs\_maxaddr is not given, then profiling is stopped and the data obtained is written to the file 'mon.out' where it can be analyzed with the UNIX 'prof' program.

NOTE: this function only works if the lisp system has been compiled in a special way, otherwise, an error is invoked.

**(opval 's\_arg ['g\_newval])**

RETURNS: the value associated with s\_arg before the call.

SIDE EFFECT: If g\_newval is specified, the value associated with s\_arg is changed to g\_newval.

NOTE: *opval* keeps track of storage allocation. If s\_arg is one of the data types then *opval* will return a list of three fixnums representing the number of items of that type in use, the number of pages allocated and the number of items of that type per page. You should never try to change the value *opval* associates with a data type using *opval*.

If s\_arg is *pagelimit* then *opval* will return (and set if g\_newval is given) the maximum amount of lisp data pages it will allocate. This limit should remain small unless you know your program requires lots of space as this limit will catch programs in infinite loops which gobble up memory.

**(\*process 'st\_command ['g\_readp ['g\_writep]])**

RETURNS: either a fixnum if one argument is given, or a list of two ports and a fixnum if two or three arguments are given.

NOTE: *\*process* starts another process by passing *st\_command* to the shell (it first tries */bin/csh*, then it tries */bin/sh* if */bin/csh* doesn't exist). If only one argument is given to *\*process*, *\*process* waits for the new process to die and then returns the exit code of the new process. If more two or three arguments are given, *\*process* starts the process and then returns a list which, depending on the value of *g\_readp* and *g\_writep*, may contain i/o ports for communicating with the new process. If *g\_writep* is non-null, then a port will be created which the lisp program can use to send characters to the new process. If *g\_readp* is non-null, then a port will be created which the lisp program can use to read characters from the new process. The value returned by *\*process* is (readport writeport pid) where readport and writeport are either nil or a port based on the value of *g\_readp* and *g\_writep*. Pid is the process id of the new process. Since it is hard to remember the order of *g\_readp* and *g\_writep*, the functions *\*process-send* and *\*process-recv* were written to perform the common functions.

**(\*process-recv 'st\_command)**

RETURNS: a port which can be read.

SIDE EFFECT: The command *st\_command* is given to the shell and it is started running in the background. The output of that command is available for reading via the port returned. The input of the command process is set to */dev/null*.

**(\*process-send 'st\_command)**

RETURNS: a port which can be written to.

SIDE EFFECT: The command *st\_command* is given to the shell and it is started running in the background. The lisp program can provide input for that command by sending characters to the port returned by this function. The output of the command process is set to */dev/null*.

**(process s\_prgm [s\_frompipe s\_topipe])**

RETURNS: if the optional arguments are not present a fixnum which is the exit code when *s\_prgm* dies. If the optional arguments are present, it returns a fixnum which is the process id of the child.

NOTE: This command is obsolete. New programs should use one of the *\*process* commands given above.

SIDE EFFECT: If *s\_frompipe* and *s\_topipe* are given, they are bound to ports which are pipes which direct characters from FRANZ LISP to the new process and to FRANZ LISP from the new process respectively. *Process* forks a process named *s\_prgm* and waits for it to die iff there are no pipe arguments given.

**(ptime)**

RETURNS: a list of two elements. The first is the amount of processor time used by the lisp system so far, and the second is the amount of time used by the garbage collector so far.

NOTE: the time is measured in those units used by the *times(2)* system call, usually *60ths* of a second. The first number includes the second number. The amount of time used by garbage collection is not recorded until the first call to *ptime*. This is done to prevent overhead when the user is not interested in garbage collection times.

**(reset)**

SIDE EFFECT: the lisp runtime stack is cleared and the system restarts at the top level by executing a (*funcall top-level nil*).

**(restorelisp 's\_name)**

SIDE EFFECT: this reads in file *s\_name* (which was created by *savelisp*) and then does a (*reset*).

NOTE: This is only used on VMS systems where *dumplisp* cannot be used.

**(retbrk ['x\_level])**

WHERE: *x\_level* is a small integer of either sign.

SIDE EFFECT: The default error handler keeps a notion of the current level of the error caught. If *x\_level* is negative, control is thrown to this default error handler whose level is that many less than the present, or to *top-level* if there aren't enough. If *x\_level* is non-negative, control is passed to the handler at that level. If *x\_level* is not present, the value -1 is taken by default.

**(\*rset 'g\_flag)**

RETURNS: *g\_flag*

SIDE EFFECT: If *g\_flag* is non nil then the lisp system will maintain extra information about calls to *eval* and *funcall*. This record keeping slows down the evaluation but this is required for the functions *evalhook*, *funcallhook*, and *evalframe* to work. To debug compiled lisp code the transfer tables should be unlinked: (*sstatus translink nil*)

**(savelisp 's\_name)**

RETURNS: *t*

SIDE EFFECT: the state of the Lisp system is saved in the file *s\_name*. It can be read in by *restorelisp*.

NOTE: This is only used on VMS systems where *dumplisp* cannot be used.

**(segment 's\_type 'x\_size)**

WHERE: *s\_type* is one of the data types given in §1.3

RETURNS: a segment of contiguous lispvals of type *s\_type*.

NOTE: In reality, *segment* returns a new data cell of type *s\_type* and allocates space for *x\_size* + 1 more *s\_type*'s beyond the one returned. *Segment* always allocates new space and does so in 512 byte chunks. If you ask for 2 fixnums, *segment* will actually allocate 128 of them thus wasting 126 fixnums. The function *small-segment* is a smarter space allocator and should be used whenever possible.

**(shell)**

RETURNS: the exit code of the shell when it dies.

SIDE EFFECT: this forks a new shell and returns when the shell dies.

**(showstack)**

RETURNS: nil

SIDE EFFECT: all forms currently in evaluation are printed, beginning with the most recent. For compiled code the most that showstack will show is the function name and it may miss some functions.

**(signal 'x\_signum 's\_name)**

RETURNS: nil if no previous call to signal has been made, or the previously installed s\_name.

SIDE EFFECT: this declares that the function named s\_name will handle the signal number x\_signum. If s\_name is nil, the signal is ignored. Presently only four UNIX signals are caught. They and their numbers are: Interrupt(2), Floating exception(8), Alarm(14), and Hang-up(1).

**(sizeof 'g\_arg)**

RETURNS: the number of bytes required to store one object of type g\_arg, encoded as a fixnum.

**(small-segment 's\_type 'x\_cells)**

WHERE: s\_type is one of fixnum, flonum and value.

RETURNS: a segment of x\_cells data objects of type s\_type.

SIDE EFFECT: This may call *segment* to allocate new space or it may be able to fill the request on a page already allocated. The value returned by *small-segment* is usually stored in the data subpart of an array object.

**(sstatus g\_type g\_val)**

RETURNS: g\_val

SIDE EFFECT: If g\_type is not one of the special sstatus codes described in the next few pages this simply sets g\_val as the value of status type g\_type in the system status property list.

**(sstatus appendmap g\_val)**

RETURNS: g\_val

SIDE EFFECT: If g\_val is non-null when *fasl* is told to create a load map, it will append to the file name given in the *fasl* command, rather than creating a new map file. The initial value is nil.

**(sstatus automatic-reset g\_val)**

RETURNS: g\_val

SIDE EFFECT: If g\_val is non-null when an error occurs which no one wants to handle, a *reset* will be done instead of entering a primitive internal break loop. The initial value is t.

**(sstatus chainatom g\_val)**

RETURNS: g\_val

SIDE EFFECT: If g\_val is non nil and a *car* or *cdr* of a symbol is done, then nil will be returned instead of an error being signaled. This only affects the interpreter, not the compiler. The initial value is nil.

**(sstatus dumpcore g\_val)**

RETURNS: g\_val

SIDE EFFECT: If g\_val is nil, FRANZ LISP tells UNIX that a segmentation violation or bus error should cause a core dump. If g\_val is non nil then FRANZ LISP will catch those errors and print a message advising the user to reset.

NOTE: The initial value for this flag is nil, and only those knowledgeable of the innards of the lisp system should ever set this flag non nil.

**(sstatus dumpmode x\_val)**

RETURNS: x\_val

SIDE EFFECT: All subsequent *dumplisp*'s will be done in mode x\_val. x\_val may be either 413 or 410 (decimal).

NOTE: the advantage of mode 413 is that the dumped Lisp can be demand paged in when first started, which will make it start faster and disrupt other users less. The initial value is 413.

**(sstatus evalhook g\_val)**

RETURNS: g\_val

SIDE EFFECT: When g\_val is non nil, this enables the evalhook and funcallhook traps in the evaluator. See §14.4 for more details.

**(sstatus feature g\_val)**

RETURNS: g\_val

SIDE EFFECT: g\_val is added to the (*status features*) list,**(sstatus gcstrings g\_val)**

RETURNS: g\_val

SIDE EFFECT: if g\_val is non-null, and if string garbage collection was enabled when the lisp system was compiled, string space will be garbage collected.

NOTE: the default value for this is nil since in most applications garbage collecting strings is a waste of time.

**(sstatus ignoreeof g\_val)**

RETURNS: g\_val

SIDE EFFECT: If g\_val is non-null when an end of file (CNTL-D on UNIX) is typed to the standard top-level interpreter, it will be ignored rather than cause the lisp system to exit. If the the standard input is a file or pipe then this has no effect, an EOF will always cause lisp to exit. The initial value is nil.

**(sstatus nofeature g\_val)**

RETURNS: g\_val

SIDE EFFECT: g\_val is removed from the status features list if it was present.

**(sstatus translink g\_val)**

RETURNS: g\_val

SIDE EFFECT: If g\_val is nil then all transfer tables are cleared and further calls through the transfer table will not cause the fast links to be set up. If g\_val is the symbol *on* then all possible transfer table entries will be linked and the flag will be set to cause fast links to be set up dynamically. Otherwise all that is done is to set the flag to cause fast links to be set up dynamically. The initial value is nil.

NOTE: For a discussion of transfer tables, see §12.8.

**(sstatus uctolc g\_val)**

RETURNS: g\_val

SIDE EFFECT: If g\_val is not nil then all unescaped capital letters in symbols read by the reader will be converted to lower case.

NOTE: This allows FRANZ LISP to be compatible with single case lisp systems (e.g. Maclisp, Interlisp and UCILisp).

**(status g\_code)**

RETURNS: the value associated with the status code g\_code if g\_code is not one of the special cases given below

**(status ctime)**

RETURNS: a symbol whose print name is the current time and date.

EXAMPLE: (*status ctime*) = |Sun Jun 29 16:51:26 1980|

NOTE: This has been made obsolete by *time-string*, described below.

**(status feature g\_val)**

RETURNS: t iff g\_val is in the status features list.

**(status features)**

RETURNS: the value of the features code, which is a list of features which are present in this system. You add to this list with (*sstatus feature 'g\_val*) and test if feature g\_feat is present with (*status feature 'g\_feat*).

**(status isatty)**

RETURNS: t iff the standard input is a terminal.

**(status localtime)**

RETURNS: a list of fixnums representing the current time.

EXAMPLE: (*status localtime*) = (3 51 13 31 6 81 5 211 1)  
means 3rd second, 51st minute, 13th hour (1 p.m), 31st day, month 6 (0 = January), year 81 (0 = 1900), day of the week 5 (0 = Sunday), 211th day of the year and daylight savings time is in effect.

**(status syntax s\_char)**

NOTE: This function should not be used. See the description of *getsyntax* (in Chapter 7) for a replacement.

**(status undeffunc)**

RETURNS: a list of all functions which transfer table entries point to but which are not defined at this point.

NOTE: Some of the undefined functions listed could be arrays which have yet to be created.

**(status version)**

RETURNS: a string which is the current lisp version name.

EXAMPLE: *(status version)* = "Franz Lisp, Opus 38.61"

**(syscall 'x\_index ['xst\_arg1 ...])**

RETURNS: the result of issuing the UNIX system call number *x\_index* with arguments *xst\_argi*.

NOTE: The UNIX system calls are described in section 2 of the UNIX Programmer's manual. If *xst\_argi* is a fixnum, then its value is passed as an argument, if it is a symbol then its pname is passed and finally if it is a string then the string itself is passed as an argument. Some useful syscalls are:

*(syscall 20)* returns process id.

*(syscall 13)* returns the number of seconds since Jan 1, 1970.

*(syscall 10 'foo)* will unlink (delete) the file foo.

**(sys:access 'st\_filename 'x\_mode)**

**(sys:chmod 'st\_filename 'x\_mode)**

**(sys:gethostname)**

**(sys:getpid)**

**(sys:getpwnam 'st\_username)**

**(sys:link 'st\_oldfilename 'st\_newfilename)**

**(sys:time)**

**(sys:unlink 'st\_filename)**

NOTE: We have been warned that the actual system call numbers may vary among different UNIX systems. Users concerned about portability may wish to use this group of functions. Another advantage is that tilde-expansion is performed on all filename arguments. These functions do what is described in the system call section of your UNIX manual.

*sys:getpwnam* returns a vector of four entries from the password file, being the user name, user id, group id, and home directory.

**(time-string ['x\_seconds])**

RETURNS: an ascii string giving the time and date which was *x\_seconds* after UNIX's idea of creation (Midnight, Jan 1, 1970 GMT). If no argument is given, *time-string* returns the current date. This supplants *(status ctime)*, and may be used to make the results of *filestat* more intelligible.

**(top-level)**

RETURNS: nothing (it never returns)

NOTE: This function is the top-level read-eval-print loop. It never returns any value. Its main utility is that if you redefine it, and do a (reset) then the redefined (top-level) is then invoked. The default top-level for Franz, allow one to specify his own printer or reader, by binding the symbols **top-level-printer** and **top-level-reader**. One can let the default top-level do most of the drudgery in catching *reset*'s, and reading in .lisprc files, by binding the symbol **user-top-level**, to a routine that concerns itself only with the read-eval-print loop.

**(wait)**

RETURNS: a dotted pair (*processid . status*) when the next child process dies.

## CHAPTER 7

### The Lisp Reader

#### 7.1. Introduction

The *read* function is responsible for converting a stream of characters into a Lisp expression. *Read* is table driven and the table it uses is called a *readtable*. The *print* function does the inverse of *read*; it converts a Lisp expression into a stream of characters. Typically the conversion is done in such a way that if that stream of characters were read by *read*, the result would be an expression equal to the one *print* was given. *Print* must also refer to the readtable in order to determine how to format its output. The *explode* function, which returns a list of characters rather than printing them, must also refer to the readtable.

A readtable is created with the *makereadtable* function, modified with the *setsyntax* function and interrogated with the *getsyntax* function. The structure of a readtable is hidden from the user - a readtable should only be manipulated with the three functions mentioned above.

There is one distinguished readtable called the *current readtable* whose value determines what *read*, *print* and *explode* do. The current readtable is the value of the symbol *readtable*. Thus it is possible to rapidly change the current syntax by lambda binding a different readtable to the symbol *readtable*. When the binding is undone, the syntax reverts to its old form.

#### 7.2. Syntax Classes

The readtable describes how each of the 128 ascii characters should be treated by the reader and printer. Each character belongs to a *syntax class* which has three properties:

character class -

Tells what the reader should do when it sees this character. There are a large number of character classes. They are described below.

separator -

Most types of tokens the reader constructs are one character long. Four token types have an arbitrary length: number (1234), symbol print name (franz), escaped symbol print name (lfranzl), and string ("franz"). The reader can easily determine when it has come to the end of one of the last two types: it just looks for the matching delimiter (l or "). When the reader is reading a number or symbol print name, it stops reading when it comes to a character with the *separator* property. The separator character is pushed back into the input stream and will be the first character read when the reader is called again.

escape -

Tells the printer when to put escapes in front of, or around, a symbol whose print name contains this character. There are three possibilities: always escape a symbol with this character in it, only escape a symbol if this is the only character in the symbol, and only escape a symbol if this is the first character in the symbol. [note: The printer will always escape a symbol which, if printed out, would look like a valid number.]

When the Lisp system is built, Lisp code is added to a C-coded kernel and the result becomes the standard Lisp system. The readtable present in the C-coded kernel, called the *raw readtable*, contains the bare necessities for reading in Lisp code. During the construction of the complete Lisp system, a copy is made of the raw readtable and then the copy is modified by adding macro

characters. The result is what is called the *standard readtable*. When a new readtable is created with *makereadtable*, a copy is made of either the raw readtable or the current readtable (which is likely to be the standard readtable).

### 7.3. Reader Operations

The reader has a very simple algorithm. It is either *scanning* for a token, *collecting* a token, or *processing* a token. Scanning involves reading characters and throwing away those which don't start tokens (such as blanks and tabs). Collecting means gathering the characters which make up a token into a buffer. Processing may involve creating symbols, strings, lists, fixnums, bignums or flonums or calling a user written function called a character macro.

The components of the syntax class determine when the reader switches between the scanning, collecting and processing states. The reader will continue scanning as long as the character class of the characters it reads is *cseparator*. When it reads a character whose character class is not *cseparator* it stores that character in its buffer and begins the collecting phase.

If the character class of that first character is *ccharacter*, *cnumber*, *cperiod*, or *csign*. then it will continue collecting until it runs into a character whose syntax class has the *separator* property. (That last character will be pushed back into the input buffer and will be the first character read next time.) Now the reader goes into the processing phase, checking to see if the token it read is a number or symbol. It is important to note that after the first character is collected the component of the syntax class which tells the reader to stop collecting is the *separator* property, not the character class.

If the character class of the character which stopped the scanning is not *ccharacter*, *cnumber*, *cperiod*, or *csign*. then the reader processes that character immediately. The character classes *csingle-macro*, *csingle-splicing-macro*, and *csingle-infix-macro* will act like *ccharacter* if the following token is not a *separator*. The processing which is done for a given character class is described in detail in the next section.

### 7.4. Character Classes

*ccharacter* raw readtable:A-Z a-z ^H !#\$%&\*./:;<=>?@^\_`{ } ~  
 standard readtable:A-Z a-z ^H !#\$%&\*./:;<=>?@^\_`{ } ~

A normal character.

*cnumber* raw readtable:0-9  
 standard readtable:0-9

This type is a digit. The syntax for an integer (fixnum or bignum) is a string of *cnumber* characters optionally followed by a *cperiod*. If the digits are not followed by a *cperiod*, then they are interpreted in base *ibase* which must be eight or ten. The syntax for a floating point number is either zero or more *cnumber*'s followed by a *cperiod* and then followed by one or more *cnumber*'s. A floating point number may also be an integer or floating point number followed by 'e' or 'd', an optional '+' or '-' and then zero or more *cnumber*'s.

*csign* raw readtable:+  
 standard readtable:+

A leading sign for a number. No other characters should be given this class.

*cleft-paren* raw readtable:(

- standard readtable:(
- A left parenthesis. Tells the reader to begin forming a list.
- cright-paren* raw readtable:)  
standard readtable:)
- A right parenthesis. Tells the reader that it has reached the end of a list.
- cleft-bracket* raw readtable:[  
standard readtable:[
- A left bracket. Tells the reader that it should begin forming a list. See the description of *cright-bracket* for the difference between cleft-bracket and cleft-paren.
- cright-bracket* raw readtable:]  
standard readtable:]
- A right bracket. A *cright-bracket* finishes the formation of the current list and all enclosing lists until it finds one which begins with a *cleft-bracket* or until it reaches the top level list.
- cperiod* raw readtable:.  
standard readtable:.
- The period is used to separate element of a cons cell [e.g. (a . (b . nil)) is the same as (a b)]. *cperiod* is also used in numbers as described above.
- cseparator* raw readtable:^I^M esc space  
standard readtable:^I^M esc space
- Separates tokens. When the reader is scanning, these character are passed over. Note: there is a difference between the *cseparator* character class and the *separator* property of a syntax class.
- csingle-quote* raw readtable:’  
standard readtable:’
- This causes *read* to be called recursively and the list (quote <value read>) to be returned.
- csymbol-delimiter* raw readtable:|  
standard readtable:|
- This causes the reader to begin collecting characters and to stop only when another identical *csymbol-delimiter* is seen. The only way to escape a *csymbol-delimiter* within a symbol name is with a *cescape* character. The collected characters are converted into a string which becomes the print name of a symbol. If a symbol with an identical print name already exists, then the allocation is not done, rather the existing symbol is used.
- cescape* raw readtable:\  
standard readtable:\
- This causes the next character to read in to be treated as a **vcharacter**. A character whose syntax class is **vcharacter** has a character class *ccharacter* and does not have the *separator* property so it will not separate symbols.
- cstring-delimiter* raw readtable:"  
standard readtable:"
- This is the same as *csymbol-delimiter* except the result is returned as a string instead of a symbol.

*csingle-character-symbol* raw readable:none  
standard readable:none

This returns a symbol whose print name is the the single character which has been collected.

*cmacro* raw readable:none  
standard readable:‘,

The reader calls the macro function associated with this character and the current readable, passing it no arguments. The result of the macro is added to the structure the reader is building, just as if that form were directly read by the reader. More details on macros are provided below.

*csplicing-macro* raw readable:none  
standard readable:#;

A *csplicing-macro* differs from a *cmacro* in the way the result is incorporated in the structure the reader is building. A *csplicing-macro* must return a list of forms (possibly empty). The reader acts as if it read each element of the list itself without the surrounding parenthesis.

*csingle-macro* raw readable:none  
standard readable:none

This causes to reader to check the next character. If it is a *cseparator* then this acts like a *cmacro*. Otherwise, it acts like a *ccharacter*.

*csingle-splicing-macro* raw readable:none  
standard readable:none

This is triggered like a *csingle-macro* however the result is spliced in like a *csplicing-macro*.

*cinfix-macro* raw readable:none  
standard readable:none

This is differs from a *cmacro* in that the macro function is passed a form representing what the reader has read so far. The result of the macro replaces what the reader had read so far.

*csingle-infix-macro* raw readable:none  
standard readable:none

This differs from the *cinfix-macro* in that the macro will only be triggered if the character following the *csingle-infix-macro* character is a *cseparator*.

*cillegal* raw readable:^@-^G^N^Z^-^\_rubout  
standard readable:^@-^G^N^Z^-^\_rubout

The characters cause the reader to signal an error if read.

## 7.5. Syntax Classes

The readable maps each character into a syntax class. The syntax class contains three pieces of information: the character class, whether this is a separator, and the escape properties. The first two properties are used by the reader, the last by the printer (and *explode*). The initial lisp system has the following syntax classes defined. The user may add syntax classes with *add-syntax-class*. For each syntax class, we list the properties of the class and which characters have this syntax class by default. More information about each syntax class can be found under the description of the syntax class's character class.

**vcharacter**  
*ccharacter*

raw readtable:A-Z a-z ^H !#\$%&\*./:;<=>?@^\_‘{}~  
standard readtable:A-Z a-z ^H !#\$%&\*./:;<=>?@^\_‘{}~

**vnumber**

<b>villegal</b> <i>cillegal</i> <i>escape-always</i>	raw readtable:^@-^G^N-^Z^-^_rubout standard readtable:^@-^G^N-^Z^-^_rubout

## 7.6. Character Macros

Character macros are user written functions which are executed during the reading process. The value returned by a character macro may or may not be used by the reader, depending on the type of macro and the value returned. Character macros are always attached to a single character with the *setsyntax* function.

**7.6.1. Types** There are three types of character macros: normal, splicing and infix. These types differ in the arguments they are given or in what is done with the result they return.

### 7.6.1.1. Normal

A normal macro is passed no arguments. The value returned by a normal macro is simply used by the reader as if it had read the value itself. Here is an example of a macro which returns the abbreviation for a given state.

---

```

[]>(defun stateabbrev nil
      (cdr (assq (read) '((california . ca) (pennsylvania . pa))))))
stateabbrev
[]>(setsyntax '\ 'vmacro 'stateabbrev)
t
[]>'(! californi ! wyoming ! pennsylvania)
(ca nil pa)

```

---

Notice what happened to

*! wyoming*. Since it wasn't in the table, the associated function returned nil. The creator of the macro may have wanted to leave the list alone, in such a case, but couldn't with this type of reader macro. The splicing macro, described next, allows a character macro function to return a value that is ignored.

### 7.6.1.2. Splicing

The value returned from a splicing macro must be a list or nil. If the value is nil, then the value is ignored, otherwise the reader acts as if it read each object in the list. Usually the list only contains one element. If the reader is reading at the top level (i.e. not collecting elements of list), then it is illegal for a splicing macro to return more than one element in the list. The major advantage of a splicing macro over a normal macro is the ability of the splicing macro to return nothing. The comment character (usually ;) is a splicing macro bound to a function which reads to the end of the line and always returns nil. Here is the previous example written as a splicing macro

---

```

[]>(defun stateabbrev nil
      ((lambda (value)
          (cond (value (list value))
                (t nil)))
       (cdr (assq (read) '((california . ca) (pennsylvania . pa))))))
[]>(setsyntax '\ 'vsplicing-macro 'stateabbrev)
[]>'(!pennsylvania !foo !california)
(pa ca)

### 7.6.1.3. Infix

Infix macros are passed a *conc* structure representing what has been read so far. Briefly, a tconc structure is a single list cell whose car points to a list and whose cdr points to the last list cell in that list. The interpretation by the reader of the value returned by an

infix macro depends on whether the macro is called while the reader is constructing a list or whether it is called at the top level of the reader. If the macro is called while a list is being constructed, then the value returned should be a `tconc` structure. The `car` of that structure replaces the list of elements that the reader has been collecting. If the macro is called at top level, then it will be passed the value `nil`, and the value it returns should either be `nil` or a `tconc` structure. If the macro returns `nil`, then the value is ignored and the reader continues to read. If the macro returns a `tconc` structure of one element (i.e. whose `car` is a list of one element), then that single element is returned as the value of `read`. If the macro returns a `tconc` structure of more than one element, then that list of elements is returned as the value of `read`.

---

```

☐> (defun plusop (x)
      (cond ((null x) (tconc nil ^+))
            (t (lconc nil (list 'plus (caar x) (read))))))

plusop
☐> (setsyntax ^+ 'infix-macro 'plusop)
t
☐> '(a + b)
(plus a b)
☐> '+
|+|
☐>

```

---

### 7.6.2. Invocations

There are three different circumstances in which you would like a macro function to be triggered.

*Always* -

Whenever the macro character is seen, the macro should be invoked. This is accomplished by using the character classes `cmacro`, `csplicing-macro`, or `cinfix-macro`, and by using the `separator` property. The syntax classes **vmacro**, **vsplicing-macro**, and **vsingle-macro** are defined this way.

*When first* -

The macro should only be triggered when the macro character is the first character found after the scanning process. A syntax class for a *when first* macro would be defined using `cmacro`, `csplicing-macro`, or `cinfix-macro` and not including the `separator` property.

*When unique* -

The macro should only be triggered when the macro character is the only character collected in the token collection phase of the reader, i.e the macro character is preceded by zero or more `cseparators` and followed by a `separator`. A syntax class for a *when unique* macro would be defined using `csingle-macro`, `csingle-splicing-macro`, or `csingle-infix-macro` and not including the `separator` property. The syntax classes so defined are **vsingle-macro**, **vsingle-splicing-macro**, and **vsingle-infix-macro**.

## 7.7. Functions

**(setsyntax 's\_symbol 's\_synclass ['ls\_func])**

WHERE: ls\_func is the name of a function or a lambda body.

RETURNS: t

SIDE EFFECT: S\_symbol should be a symbol whose print name is only one character. The syntax class for that character is set to s\_synclass in the current readtable. If s\_synclass is a class that requires a character macro, then ls\_func must be supplied.

NOTE: The symbolic syntax codes are new to Opus 38. For compatibility, s\_synclass can be one of the fixnum syntax codes which appeared in older versions of the FRANZ LISP Manual. This compatibility is only temporary: existing code which uses the fixnum syntax codes should be converted.

**(getsyntax 's\_symbol)**

RETURNS: the syntax class of the first character of s\_symbol's print name. s\_symbol's print name must be exactly one character long.

NOTE: This function is new to Opus 38. It supercedes (*status syntax*) which no longer exists.

**(add-syntax-class 's\_synclass 'l\_properties)**

RETURNS: s\_synclass

SIDE EFFECT: Defines the syntax class s\_synclass to have properties l\_properties. The list l\_properties should contain a character classes mentioned above. l\_properties may contain one of the escape properties: *escape-always*, *escape-when-unique*, or *escape-when-first*. l\_properties may contain the *separator* property. After a syntax class has been defined with *add-syntax-class*, the *setsyntax* function can be used to give characters that syntax class.

---

```

; Define a non-separating macro character.
; This type of macro character is used in UCI-Lisp, and
; it corresponds to a FIRST MACRO in Interlisp
[]> (add-syntax-class 'vuci-macro '(cmacro escape-when-first))
vuci-macro
[]>

```

---

## CHAPTER 8

### Functions, Fclosures, and Macros

#### 8.1. valid function objects

There are many different objects which can occupy the function field of a symbol object. Table 8.1, on the following page, shows all of the possibilities, how to recognize them, and where to look for documentation.

#### 8.2. functions

The basic Lisp function is the lambda function. When a lambda function is called, the actual arguments are evaluated from left to right and are lambda-bound to the formal parameters of the lambda function.

An nlambda function is usually used for functions which are invoked by the user at top level. Some built-in functions which evaluate their arguments in special ways are also nlambda (e.g. *cond*, *do*, *or*). When an nlambda function is called, the list of unevaluated arguments is lambda bound to the single formal parameter of the nlambda function.

Some programmers will use an nlambda function when they are not sure how many arguments will be passed. Then, the first thing the nlambda function does is map *eval* over the list of unevaluated arguments it has been passed. This is usually the wrong thing to do, as it will not work compiled if any of the arguments are local variables. The solution is to use a lexpr. When a lexpr function is called, the arguments are evaluated and a fixnum whose value is the number of arguments is lambda-bound to the single formal parameter of the lexpr function. The lexpr can then access the arguments using the *arg* function.

When a function is compiled, *special* declarations may be needed to preserve its behavior. An argument is not lambda-bound to the name of the corresponding formal parameter unless that formal parameter has been declared *special* (see §12.3.2.2).

Lambda and lexpr functions both compile into a binary object with a discipline of lambda. However, a compiled lexpr still acts like an interpreted lexpr.

#### 8.3. macros

An important feature of Lisp is its ability to manipulate programs as data. As a result of this, most Lisp implementations have very powerful macro facilities. The Lisp language's macro facility can be used to incorporate popular features of the other languages into Lisp. For example, there are macro packages which allow one to create records (ala Pascal) and refer to elements of those records by the field names. The *struct* package imported from Maclisp does this. Another popular use for macros is to create more readable control structures which expand into *cond*, *or* and *and*. One such example is the *If* macro. It allows you to write

```
(If (equal numb 0) then (print 'zero) (terpr)
    elseif (equal numb 1) then (print 'one) (terpr))
```

informal name	object type	documentation
interpreted lambda function	list with <i>car</i> <i>eq</i> to lambda	8.2
interpreted nlambda function	list with <i>car</i> <i>eq</i> to nlambda	8.2
interpreted lexpr function	list with <i>car</i> <i>eq</i> to lexpr	8.2

*else (print 'I give up!))*

which expands to

```
(cond
  ((equal numb 0) (print 'zero) (terpr))
  ((equal numb 1) (print 'one) (terpr))
  (t (print 'I give up!)))
```

---

<sup>†</sup>Only the first character of the string is significant (i.e. “s” is ok for “subroutine”)

### 8.3.1. macro forms

A macro is a function which accepts a Lisp expression as input and returns another Lisp expression. The action the macro takes is called macro expansion. Here is a simple example:

```

[]> (def first (macro (x) (cons 'car (cdr x))))
first
[]> (first '(a b c))
a
[]> (apply 'first '(first '(a b c)))
(car '(a b c))

```

The first input line defines a macro called *first*. Notice that the macro has one formal parameter, *x*. On the second input line, we ask the interpreter to evaluate *(first '(a b c))*. *Eval* sees that *first* has a function definition of type macro, so it evaluates *first*'s definition, passing to *first*, as an argument, the form *eval* itself was trying to evaluate: *(first '(a b c))*. The *first* macro chops off the car of the argument with *cdr*, cons' a *car* at the beginning of the list and returns *(car '(a b c))*, which *eval* evaluates. The value *a* is returned as the value of *(first '(a b c))*. Thus whenever *eval* tries to evaluate a list whose car has a macro definition it ends up doing (at least) two operations, the first of which is a call to the macro to let it macro expand the form, and the other is the evaluation of the result of the macro. The result of the macro may be yet another call to a macro, so *eval* may have to do even more evaluations until it can finally determine the value of an expression. One way to see how a macro will expand is to use *apply* as shown on the third input line above.

### 8.3.2. defmacro

The macro *defmacro* makes it easier to define macros because it allows you to name the arguments to the macro call. For example, suppose we find ourselves often writing code like *(setq stack (cons newelt stack))*. We could define a macro named *push* to do this for us. One way to define it is:

```

[]> (def push
      (macro (x) (list 'setq (caddr x) (list 'cons (cadr x) (caddr x))))
push

```

then *(push newelt stack)* will expand to the form mentioned above. The same macro written using *defmacro* would be:

```

[]> (defmacro push (value stack)
      (list 'setq ,stack (list 'cons ,value ,stack)))
push

```

*Defmacro* allows you to name the arguments of the macro call, and makes the macro definition look more like a function definition.

### 8.3.3. the backquote character macro

The default syntax for FRANZ LISP has four characters with associated character macros. One is semicolon for comments. Two others are the backquote and comma which are used by the backquote character macro. The fourth is the sharp sign macro described in the next section.

The backquote macro is used to create lists where many of the elements are fixed (quoted). This makes it very useful for creating macro definitions. In the simplest case, a

backquote acts just like a single quote:

```
□>'(a b c d e)
(a b c d e)
```

If a comma precedes an element of a backquoted list then that element is evaluated and its value is put in the list.

```
□>(setq d '(x y z))
(x y z)
□>'(a b c ,d e)
(a b c (x y z) e)
```

If a comma followed by an at sign precedes an element in a backquoted list, then that element is evaluated and spliced into the list with *append*.

```
□>'(a b c ,@d e)
(a b c x y z e)
```

Once a list begins with a backquote, the commas may appear anywhere in the list as this example shows:

```
□>'(a b (c d ,(cdr d)) (e f (g h ,(cddr d) ,@d)))
(a b (c d (y z)) (e f (g h z x y z)))
```

It is also possible and sometimes even useful to use the backquote macro within itself. As a final demonstration of the backquote macro, we shall define the first and push macros using all the power at our disposal: defmacro and the backquote macro.

```
□>(defmacro first (list) `(car ,list))
first
□>(defmacro push (value stack) `(setq ,stack (cons ,value ,stack)))
stack
```

### 8.3.4. sharp sign character macro

The sharp sign macro can perform a number of different functions at read time. The character directly following the sharp sign determines which function will be done, and following Lisp s-expressions may serve as arguments.

#### 8.3.4.1. conditional inclusion

If you plan to run one source file in more than one environment then you may want to some pieces of code to be included or not included depending on the environment. The C language uses “#ifdef” and “#ifndef” for this purpose, and Lisp uses “#+” and “#[]”. The environment that the sharp sign macro checks is the (*status features*) list which is initialized when the Lisp system is built and which may be altered by (*sstatus feature foo*) and (*sstatus nofeature bar*) The form of conditional inclusion is

```
#+when what
```

where *when* is either a symbol or an expression involving symbols and the functions *and*, *or*, and *not*. The meaning is that *what* will only be read in if *when* is true. A symbol in *when* is true only if it appears in the (*status features*) list.

---

```

; suppose we want to write a program which references a file
; and which can run at ucb, ucsd and cmu where the file naming conventions
; are different.
;
[]> (defun howold (name)
      (terpr)
      (load #+(or ucb ucsd) "/usr/lib/lisp/ages.l"
            #+cmu "/usr/lisp/doc/ages.l")
      (patom name)
      (patom " is ")
      (print (cdr (assoc name agefile)))
      (patom "years old")
      (terpr))

```

---

The form

`#[]when what`

is equivalent to

`#+(not when) what`

#### 8.3.4.2. fixnum character equivalents

When working with fixnum equivalents of characters, it is often hard to remember the number corresponding to a character. The form

`#/c`

is equivalent to the fixnum representation of character `c`.

---

```

; a function which returns t if the user types y else it returns nil.
;
[]> (defun yesorno nil
      (progn (ans)
             (setq ans (tyi))
             (cond ((equal ans #/y) t)
                   (t nil))))

```

---

#### 8.3.4.3. read time evaluation

Occasionally you want to express a constant as a Lisp expression, yet you don't want to pay the penalty of evaluating this expression each time it is referenced. The form

`#.expression`

evaluates the expression at read time and returns its value.

---

```

; a function to test if any of bits 1 3 or 12 are set in a fixnum.
;
[]> (defun testit (num)
      (cond ((zerop (boole 1 num #.(+ (lsh 1 1) (lsh 1 3) (lsh 1 12))))
            (nil)
            (t t)))

```

---

## 8.4. fclosures

Fclosures are a type of functional object. The purpose is to remember the values of some variables between invocations of the functional object and to protect this data from being inadvertently overwritten by other Lisp functions. Fortran programs usually exhibit this behavior for their variables. (In fact, some versions of Fortran would require the variables to be in COMMON). Thus it is easy to write a linear congruent random number generator in Fortran, merely by keeping the seed as a variable in the function. It is much more risky to do so in Lisp, since any special variable you picked, might be used by some other function. Fclosures are an attempt to provide most of the same functionality as closures in Lisp Machine Lisp, to users of FRANZ LISP. Fclosures are related to closures in this way:

```

(fclosure '(a b) 'foo) <==>
      (let ((a a) (b b)) (closure '(a b) 'foo))

```

### 8.4.1. an example

---

```

% lisp
Franz Lisp, Opus 38.60
[]>(defun code (me count)
      (print (list 'in x))
      (setq x (+ 1 x))
      (cond ((greaterp count 1) (funcall me me (sub1 count))))
      (print (list 'out x)))
code
[]>(defun tester (object count)
      (funcall object object count) (terpri))
tester
[]>(setq x 0)
0
[]>(setq z (fclosure '(x) 'code))
fclosure[8]
[]> (tester z 3)
(in 0)(in 1)(in 2)(out 3)(out 3)(out 3)
nil
[]>x
0

```

---

The function *fclosure* creates a new object that we will call an fclosure, (although it is actually a vector). The fclosure contains a functional object, and a set of symbols and values for

the symbols. In the above example, the fclosure functional object is the function code. The set of symbols and values just contains the symbol 'x' and zero, the value of 'x' when the fclosure was created.

When an fclosure is funcall'ed:

- 1) The Lisp system lambda binds the symbols in the fclosure to their values in the fclosure.
- 2) It continues the funcall on the functional object of the fclosure.
- 3) Finally, it un-lambda binds the symbols in the fclosure and at the same time stores the current values of the symbols in the fclosure.

Notice that the fclosure is saving the value of the symbol 'x'. Each time a fclosure is created, new space is allocated for saving the values of the symbols. Thus if we execute fclosure again, over the same function, we can have two independent counters:

---

```

☞ (setq zz (fclosure '(x) 'code))
fclosure[1]
☞ (tester zz 2)
(in 0)(in 1)(out 2)(out 2)
☞ (tester zz 2)
(in 2)(in 3)(out 4)(out 4)
☞ (tester z 3)
(in 3)(in 4)(in 5)(out 6)(out 6)(out 6)

```

---

#### 8.4.2. useful functions

Here are some quick some summaries of functions dealing with closures. They are more formally defined in §2.8.4. To recap, fclosures are made by (*fclosure* '*l\_vars*' *g\_funcobj*). *l\_vars* is a list of symbols (not containing nil), *g\_funcobj* is any object that can be funcalled. (Objects which can be funcalled, include compiled Lisp functions, lambda expressions, symbols, foreign functions, etc.) In general, if you want a compiled function to be closed over a variable, you must declare the variable to be special within the function. Another example would be:

```
(fclosure '(a b) #'(lambda (x) (plus x a)))
```

Here, the #' construction will make the compiler compile the lambda expression.

There are times when you want to share variables between fclosures. This can be done if the fclosures are created at the same time using *fclosure-list*. The function *fclosure-alist* returns an assoc list giving the symbols and values in the fclosure. The predicate *fclosurep* returns t iff its argument is a fclosure. Other functions imported from Lisp Machine Lisp are *symeval-in-fclosure*, *let-fclosure*, and *set-in-fclosure*. Lastly, the function *fclosure-function* returns the function argument.

#### 8.4.3. internal structure

Currently, closures are implemented as vectors, with property being the symbol fclosure. The functional object is the first entry. The remaining entries are structures which point to the symbols and values for the closure, (with a reference count to determine if a recursive closure is active).

### 8.5. foreign subroutines and functions

FRANZ LISP has the ability to dynamically load object files produced by other compilers and to call functions defined in those files. These functions are called *foreign* functions.\* There are seven types of foreign functions. They are characterized by the type of result they return, and by differences in the interpretation of their arguments. They come from two families: a group suited for languages which pass arguments by reference (e.g. Fortran), and a group suited for languages which pass arguments by value (e.g. C).

There are four types in the first group:

#### subroutine

This does not return anything. The Lisp system always returns t after calling a subroutine.

#### function

This returns whatever the function returns. This must be a valid Lisp object or it may cause the Lisp system to fail.

#### integer-function

This returns an integer which the Lisp system makes into a fixnum and returns.

#### real-function

This returns a double precision real number which the Lisp system makes into a flonum and returns.

There are three types in the second group:

#### c-function

This is like an integer function, except for its different interpretation of arguments.

#### double-c-function

This is like a real-function.

#### vector-c-function

This is for C functions which return a structure. The first argument to such functions must be a vector (of type `vectori`), into which the result is stored. The second Lisp argument becomes the first argument to the C function, and so on

A foreign function is accessed through a binary object just like a compiled Lisp function. The difference is that the discipline field of a binary object for a foreign function is a string whose first character is given in the following table:

letter	type
s	subroutine
f	function
i	integer-function
r	real-function.
c	c-function
v	vector-c-function
d	double-c-function

Two functions are provided for setting-up foreign functions. *Cfasl* loads an object file into the Lisp system and sets up one foreign function binary object. If there are more than one function in an object file, *getaddress* can be used to set up additional foreign function objects.

Foreign functions are called just like other functions, e.g. (*funname arg1 arg2*). When a function in the Fortran group is called, the arguments are evaluated and then examined. List, hunk

---

\*This topic is also discussed in Report PAM-124 of the Center for Pure and Applied Mathematics, UCB, entitled "Parlez-Vous Franz? An Informal Introduction to Interfacing Foreign Functions to Franz LISP", by James R. Larus

and symbol arguments are passed unchanged to the foreign function. Fixnum and flonum arguments are copied into a temporary location and a pointer to the value is passed (this is because Fortran uses call by reference and it is dangerous to modify the contents of a fixnum or flonum which something else might point to). If the argument is an array object, the data field of the array object is passed to the foreign function (This is the easiest way to send large amounts of data to and receive large amounts of data from a foreign function). If a binary object is an argument, the entry field of that object is passed to the foreign function (the entry field is the address of a function, so this amounts to passing a function as an argument).

When a function in the C group is called, fixnum and flonum arguments are passed by value. For almost all other arguments, the address is merely provided to the C routine. The only exception arises when you want to invoke a C routine which expects a “structure” argument. Recall that a (rarely used) feature of the C language is the ability to pass structures by value. This copies the structure onto the stack. Since the Franz’s nearest equivalent to a C structure is a vector, we provide an escape clause to copy the contents of an immediate-type vector by value. If the property field of a vector argument, is the symbol “value-structure-argument”, then the binary data of this immediate-type vector is copied into the argument list of the C routine.

The method a foreign function uses to access the arguments provided by Lisp is dependent on the language of the foreign function. The following scripts demonstrate how how Lisp can interact with three languages: C, Pascal and Fortran. C and Pascal have pointer types and the first script shows how to use pointers to extract information from Lisp objects. There are two functions defined for each language. The first (cfoo in C, pfoo in Pascal) is given four arguments, a fixnum, a flonum-block array, a hunk of at least two fixnums and a list of at least two fixnums. To demonstrate that the values were passed, each ?foo function prints its arguments (or parts of them). The ?foo function then modifies the second element of the flonum-block array and returns a 3 to Lisp. The second function (cmemq in C, pmemq in Pascal) acts just like the Lisp *memq* function (except it won’t work for fixnums whereas the lisp *memq* will work for small fixnums). In the script, typed input is in **bold**, computer output is in roman and comments are in *italic*.

---

*These are the C coded functions*

```
% cat ch8auxc.c
/* demonstration of c coded foreign integer-function */

/* the following will be used to extract fixnums out of a list of fixnums */
struct listoffixnumscell
{
    struct listoffixnumscell *cdr;
    int *fixnum;
};

struct listcell
{
    struct listcell *cdr;
    int car;
};

cfoo(a,b,c,d)
int *a;
double b[];
int *c[];
struct listoffixnumscell *d;
{
    printf("a: %d, b[0]: %f, b[1]: %f\n", *a, b[0], b[1]);
    printf(" c (first): %d  c (second): %d\n",
           *c[0], *c[1]);
    printf(" ( %d %d ... ) ", *(d->fixnum), *(d->cdr->fixnum));
    b[1] = 3.1415926;
    return(3);
}

struct listcell *
cmemq(element,list)
```

```

int element;
struct listcell *list;
{
  for( ; list && element != list->car ; list = list->cdr);
  return(list);
}

```

*These are the Pascal coded functions*

**% cat ch8auxp.p**

```

type
  pinteger = ^integer;

```

/usr/lib/lisp/nld -N -A /tmp/Li7055.0 -T 63200 ch8auxp.o -e _pfoo -o /tmp/Li7055.1 -lpc -lc

```

```

#63200-"integer-function"

```

*Here we set up the other foreign function binary objects*

```

[> (getaddress '_cmemq 'cmemq "function" '_pmemq 'pmemq "function")

```

```

#6306c-"function"

```

*We want to create and initialize an array to pass to the cfoo function. In this case we create an unnamed array and store it in the value cell of testarr. When we create an array to pass to the Pascal program we will use a named array just to demonstrate the different way that named and unnamed arrays are created and accessed.*

```

☞ (setq testarr (array nil flonum-block 2))
array[2]
☞ (store (funcall testarr 0) 1.234)
1.234
☞ (store (funcall testarr 1) 5.678)
5.678
☞ (cfoo 385 testarr (hunk 10 11 13 14) '(15 16 17))
a: 385, b[0]: 1.234000, b[1]: 5.678000
c (first): 10 c (second): 11
( 15 16 ... )
3

```

Note that *cfoo* has returned 3 as it should. It also had the side effect of changing the second value of the array to 3.1415926 which check next.

```

☞ (funcall testarr 1)
3.1415926

```

In preparation for calling *pfoo* we create an array.

```

☞ (array test flonum-block 2)
array[2]
☞ (store (test 0) 1.234)
1.234
☞ (store (test 1) 5.678)
5.678
☞ (pfoo 385 (getd 'test) (hunk 10 11 13 14) '(15 16 17))
a: 385 b[0]: 1.2340000000000000E+00 b[1]: 5.6780000000000000E+00
c (first): 10 c (second): 11
( 15 16 ... )
3
☞ (test 1)
3.1415926

```

Now to test out the *memq*'s

```

☞ (cmemq 'a '(b c a d e f))
(a d e f)
☞ (pmemq 'e '(a d f g a x))
nil

```

The Fortran example will be much shorter since in Fortran you can't follow pointers as you can in other languages. The Fortran function *ffoo* is given three arguments: a *fixnum*, a *fixnum-block* array and a *flonum*. These arguments are printed out to verify that they made it and then the first value of the array is modified. The function returns a double precision value which is converted to a *flonum* by lisp and printed. Note that the entry point corresponding to the Fortran function *ffoo* is *\_ffoo\_* as opposed to the C and Pascal convention of preceding the name with an underscore.

```

% cat ch8auxf.f
double precision function ffoo(a,b,c)
integer a,b(10)
double precision c
print 2,a,b(1),b(2),c
2 format(' a=',i4,', b(1)=',i5,', b(2)=',i5,' c=',f6.4)
b(1) = 22
ffoo = 1.23456
return
end

% f77 -c ch8auxf.f
ch8auxf.f:
ffoo:
0.9u 1.8s 0:12 22% 20+22k 54+48io 158pf+0w

```

% **lisp**

## CHAPTER 9

### Arrays and Vectors

Arrays and vectors are two means of expressing aggregate data objects in FRANZ LISP. Vectors may be thought of as sequences of data. They are intended as a vehicle for user-defined data types. This use of vectors is still experimental and subject to revision. As a simple data structure, they are similar to hunks and strings. Vectors are used to implement closures, and are useful to communicate with foreign functions. Both of these topics were discussed in Chapter 8. Later in this chapter, we describe the current implementation of vectors, and will advise the user what is most likely to change.

Arrays in FRANZ LISP provide a programmable data structure access mechanism. One possible use for FRANZ LISP arrays is to implement Maclisp style arrays which are simple vectors of fixnums, flonums or general lisp values. This is described in more detail in §9.3 but first we will describe how array references are handled by the lisp system.

The structure of an array object is given in §1.3.10 and reproduced here for your convenience.

Subpart name	Get value	Set value	Type
access function	getaccess	putaccess	binary, list or symbol
auxiliary	getaux	putaux	lispval
data	arrayref	replace set	block of contiguous lispval
length	getlength	putlength	fixnum
delta	getdelta	putdelta	fixnum

**9.1. general arrays** Suppose the evaluator is told to evaluate  $(foo\ a\ b)$  and the function cell of the symbol `foo` contains an array object (which we will call `foo_arr_obj`). First the evaluator will evaluate and stack the values of  $a$  and  $b$ . Next it will stack the array object `foo_arr_obj`. Finally it will call the access function of `foo_arr_obj`. The access function should be a `lexpr`<sup>†</sup> or a symbol whose function cell contains a `lexpr`. The access function is responsible for locating and returning a value from the array. The array access function is free to interpret the arguments as it wishes. The Maclisp compatible array access function which is provided in the standard FRANZ LISP system interprets the arguments as subscripts in the same way as languages like Fortran and Pascal.

The array access function will also be called upon to store elements in the array. For example,  $(store\ (foo\ a\ b)\ c)$  will automatically expand to  $(foo\ c\ a\ b)$  and when the evaluator is called to evaluate this, it will evaluate the arguments  $c$ ,  $b$  and  $a$ . Then it will stack the array object (which is stored in the function cell of `foo`) and call the array access function with (now) four arguments. The array access function must be able to tell this is a store operation, which it can do by checking the number of arguments it has been given (a `lexpr` can do this very easily).

---

<sup>†</sup>A `lexpr` is a function which accepts any number of arguments which are evaluated before the function is called.

**9.2. subparts of an array object** An array is created by allocating an array object with *marray* and filling in the fields. Certain lisp functions interpret the values of the subparts of the array object in special ways as described in the following text. Placing illegal values in these subparts may cause the lisp system to fail.

**9.2.1. access function** The purpose of the access function has been described above. The contents of the access function should be a lexpr, either a binary (compiled function) or a list (interpreted function). It may also be a symbol whose function cell contains a function definition. This subpart is used by *eval*, *funcall*, and *apply* when evaluating array references.

**9.2.2. auxiliary** This can be used for any purpose. If it is a list and the first element of that list is the symbol *unmarked\_array* then the data subpart will not be marked by the garbage collector (this is used in the Maclisp compatible array package and has the potential for causing strange errors if used incorrectly).

**9.2.3. data** This is either nil or points to a block of data space allocated by *segment* or *small-segment*.

**9.2.4. length** This is a fixnum whose value is the number of elements in the data block. This is used by the garbage collector and by *arrayref* to determine if your index is in bounds.

**9.2.5. delta** This is a fixnum whose value is the number of bytes in each element of the data block. This will be four for an array of fixnums or value cells, and eight for an array of flonums. This is used by the garbage collector and *arrayref* as well.

### 9.3. The Maclisp compatible array package

A Maclisp style array is similar to what is known as arrays in other languages: a block of homogeneous data elements which is indexed by one or more integers called subscripts. The data elements can be all fixnums, flonums or general lisp objects. An array is created by a call to the function *array* or *\*array*. The only difference is that *\*array* evaluates its arguments. This call: *(array foo t 3 5)* sets up an array called *foo* of dimensions 3 by 5. The subscripts are zero based. The first element is *(foo 0 0)*, the next is *(foo 0 1)* and so on up to *(foo 2 4)*. The *t* indicates a general lisp object array which means each element of *foo* can be any type. Each element can be any type since all that is stored in the array is a pointer to a lisp object, not the object itself. *Array* does this by allocating an array object with *marray* and then allocating a segment of 15 consecutive value cells with *small-segment* and storing a pointer to that segment in the data subpart of the array object. The length and delta subpart of the array object are filled in (with 15 and 4 respectively) and the access function subpart is set to point to the appropriate array access function. In this case there is a special access function for two dimensional value cell arrays called *arrac-twoD*, and this access function is used. The auxiliary subpart is set to *(t 3 5)* which describes the type of array and the bounds of the subscripts. Finally this array object is placed in the function cell of the symbol *foo*. Now when *(foo 1 3)* is evaluated, the array access function is invoked with three arguments: 1, 3 and the array object. From the auxiliary field of the array object it gets a description of the

particular array. It then determines which element (*foo 1 3*) refers to and uses `arrayref` to extract that element. Since this is an array of value cells, what `arrayref` returns is a value cell whose value is what we want, so we evaluate the value cell and return it as the value of (*foo 1 3*).

In Maclisp the call (*array foo fixnum 25*) returns an array whose data object is a block of 25 memory words. When fixnums are stored in this array, the actual numbers are stored instead of pointers to the numbers as is done in general lisp object arrays. This is efficient under Maclisp but inefficient in FRANZ LISP since every time a value was referenced from an array it had to be copied and a pointer to the copy returned to prevent aliasing<sup>†</sup>. Thus t, fixnum and flonum arrays are all implemented in the same manner. This should not affect the compatibility of Maclisp and FRANZ LISP. If there is an application where a block of fixnums or flonums is required, then the exact same effect of fixnum and flonum arrays in Maclisp can be achieved by using `fixnum-block` and `flonum-block` arrays. Such arrays are required if you want to pass a large number of arguments to a Fortran or C coded function and then get answers back.

The Maclisp compatible array package is just one example of how a general array scheme can be implemented. Another type of array you could implement would be hashed arrays. The subscript could be anything, not just a number. The access function would hash the subscript and use the result to select an array element. With the generality of arrays also comes extra cost; if you just want a simple aggregate of (less than 128) general lisp objects you would be wise to look into using hunks.

**9.4. vectors** Vectors were invented to fix two shortcomings with hunks. They can be longer than 128 elements. They also have a tag associated with them, which is intended to say, for example, "Think of me as an *Blobit*." Thus a **vector** is an arbitrary sized hunk with a property list.

Continuing the example, the lisp kernel may not know how to print out or evaluate *blobits*, but this is information which will be common to all *blobits*. On the other hand, for each individual *blobits* there are particulars which are likely to change, (height, weight, eye-color). This is the part that would previously have been stored in the individual entries in the hunk, and are stored in the data slots of the vector. Once again we summarize the structure of a vector in tabular form:

Subpart name	Get value	Set value	Type
<code>datum[i]</code>	<code>vref</code>	<code>vset</code>	<code>lispval</code>
<code>property</code>	<code>vprop</code>	<code>vsetprop</code> <code>vputprop</code>	<code>lispval</code>
<code>size</code>	<code>vsize</code>	□	<code>fixnum</code>

Vectors are created specifying size and optional fill value using the function (`new-vector 'x_size ['g_fill ['g_prop]]`), or by initial values: (`vector ['g_val ...]`).

**9.5. anatomy of vectors** There are some technical details about vectors, that the user should know:

---

<sup>†</sup>Aliasing is when two variables share the same storage location. For example if the copying mentioned weren't done then after (`setq x (foo 2)`) was done, the value of `x` and (`foo 2`) would share the same location. Then should the value of (`foo 2`) change, `x`'s value would change as well. This is considered dangerous and as a result pointers are never returned into the data space of arrays.

**9.5.1. size** The user is not free to alter this. It is noted when the vector is created, and is used by the garbage collector. The garbage collector will coalesce two free vectors, which are neighbors in the heap. Internally, this is kept as the number of bytes of data. Thus, a vector created by (*vector* 'foo), has a size of 4.

**9.5.2. property** Currently, we expect the property to be either a symbol, or a list whose first entry is a symbol. The symbols **fclosure** and **structure-value-argument** are magic, and their effect is described in Chapter 8. If the property is a (non-null) symbol, the vector will be printed out as <symbol>[<size>]. Another case is if the property is actually a (disembodied) property-list, which contains a value for the indicator **print**. The value is taken to be a Lisp function, which the printer will invoke with two arguments: the vector and the current output port. Otherwise, the vector will be printed as vector[<size>]. We have vague (as yet unimplemented) ideas about similar mechanisms for evaluation properties. Users are cautioned against putting anything other than nil in the property entry of a vector.

**9.5.3. internal order** In memory, vectors start with a longword containing the size (which is immediate data within the vector). The next cell contains a pointer to the property. Any remaining cells (if any) are for data. Vectors are handled differently from any other object in FRANZ LISP, in that a pointer to a vector is pointer to the first data cell, i.e. a pointer to the *third* longword of the structure. This was done for efficiency in compiled code and for uniformity in referencing immediate-vectors (described below). The user should never return a pointer to any other part of a vector, as this may cause the garbage collector to follow an invalid pointer.

**9.6. immediate-vectors** Immediate-vectors are similar to vectors. They differ, in that binary data are stored in space directly within the vector. Thus the garbage collector will preserve the vector itself (if used), and will only traverse the property cell. The data may be referenced as longwords, shortwords, or even bytes. Shorts and bytes are returned sign-extended. The compiler open-codes such references, and will avoid boxing the resulting integer data, where possible. Thus, immediate vectors may be used for efficiently processing character data. They are also useful in storing results from functions written in other languages.

Subpart name	Get value	Set value	Type
datum[ <i>i</i> ]	vrefi-byte vrefi-word vrefi-long	vseti-byte vseti-word vseti-long	fixnum fixnum fixnum
property	vprop	vsetprop vputprop	lispval
size	vsize vsize-byte vsize-word	□	fixnum fixnum fixnum

To create immediate vectors specifying size and fill data, you can use the functions *new-vectori-byte*, *new-vectori-word*, or *new-vectori-long*. You can also use the functions *vectori-byte*, *vectori-word*, or *vectori-long*. All of these functions are described in chapter 2.

## CHAPTER 10

### Exception Handling

#### 10.1. Errset and Error Handler Functions

FRANZ LISP allows the user to handle in a number of ways the errors which arise during computation. One way is through the use of the *errset* function. If an error occurs during the evaluation of the *errset*'s first argument, then the locus of control will return to the *errset* which will return nil (except in special cases, such as *err*). The other method of error handling is through an error handler function. When an error occurs, the error handler is called and is given as an argument a description of the error which just occurred. The error handler may take one of the following actions:

- (1) it could take some drastic action like a *reset* or a *throw*.
- (2) it could, assuming that the error is continuable, return to the function which noticed the error. The error handler indicates that it wants to return a value from the error by returning a list whose *car* is the value it wants to return.
- (3) it could decide not to handle the error and return a non-list to indicate this fact.

#### 10.2. The Anatomy of an error

Each error is described by a list of these items:

- (1) error type - This is a symbol which indicates the general classification of the error. This classification may determine which function handles this error.
- (2) unique id - This is a fixnum unique to this error.
- (3) continuable - If this is non-nil then this error is continuable. There are some who feel that every error should be continuable and the reason that some (in fact most) errors in FRANZ LISP are not continuable is due to the laziness of the programmers.
- (4) message string - This is a symbol whose print name is a message describing the error.
- (5) data - There may be from zero to three lisp values which help describe this particular error. For example, the unbound variable error contains one datum value, the symbol whose value is unbound. The list describing that error might look like:

(ER%misc 0 t |Unbound Variable:| foobar)

#### 10.3. Error handling algorithm

This is the sequence of operations which is done when an error occurs:

- (1) If the symbol **ER%all** has a non nil value then this value is the name of an error handler function. That function is called with a description of the error. If that function returns (and of course it may choose not to) and the value is a list and this error is continuable, then we return the *car* of the list to the function which called the error. Presumably the function will use this value to retry the operation. On the other hand, if the error handler returns a non list, then it has chosen not to handle this error, so we go on to step (2). Something

special happens before we call the **ER%all** error handler which does not happen in any of the other cases we will describe below. To help insure that we don't get infinitely recursive errors if **ER%all** is set to a bad value, the value of **ER%all** is set to nil before the handler is called. Thus it is the responsibility of the **ER%all** handler to 'reenable' itself by storing its name in **ER%all**.

- (2) Next the specific error handler for the type of error which just occurred is called (if one exists) to see if it wants to handle the error. The names of the handlers for the specific types of errors are stored as the values of the symbols whose names are the types. For example the handler for miscellaneous errors is stored as the value of **ER%misc**. Of course, if **ER%misc** has a value of nil, then there is no error handler for this type of error. Appendix B contains list of all error types. The process of classifying the errors is not complete and thus most errors are lumped into the **ER%misc** category. Just as in step (1), the error handler function may choose not to handle the error by returning a non-list, and then we go to step (3).
- (3) Next a check is made to see if there is an *errset* surrounding this error. If so the second argument to the *errset* call is examined. If the second argument was not given or is non nil then the error message associated with this error is printed. Finally the stack is popped to the context of the *errset* and then the *errset* returns nil. If there was no *errset* we go to step (4).
- (4) If the symbol **ER%tpl** has a value then it is the name of an error handler which is called in a manner similar to that discussed above. If it chooses not to handle the error, we go to step (5).
- (5) At this point it has been determined that the user doesn't want to handle this error. Thus the error message is printed out and a *reset* is done to send the flow of control to the top-level.

To summarize the error handling system: When an error occurs, you have two chances to handle it before the search for an *errset* is done. Then, if there is no *errset*, you have one more chance to handle the error before control jumps to the top level. Every error handler works in the same way: It is given a description of the error (as described in the previous section). It may or may not return. If it returns, then it returns either a list or a non-list. If it returns a list and the error is continuable, then the *car* of the list is returned to the function which noticed the error. Otherwise the error handler has decided not to handle the error and we go on to something else.

#### 10.4. Default aids

There are two standard error handlers which will probably handle the needs of most users. One of these is the lisp coded function *break-err-handler* which is the default value of **ER%tpl**. Thus when all other handlers have ignored an error, *break-err-handler* will take over. It will print out the error message and go into a read-eval-print loop. The other standard error handler is *debug-err-handler*. This handler is designed to be connected to **ER%all** and is useful if your program uses *errset* and you want to look at the error before it is thrown up to the *errset*.

#### 10.5. Autoloading

When *eval*, *apply* or *funcall* are told to call an undefined function, an **ER%undef** error is signaled. The default handler for this error is *undef-func-handler*. This function checks the property list of the undefined function for the indicator *autoload*. If present, the value of that indicator should be the name of the file which contains the definition of the undefined function. *Undef-func-handler* will load the file and check if it has defined the function which caused the error. If it has, the error handler will return and the computation will continue as if the error did not occur. This provides a way for the user to tell the lisp system about the location of commonly used functions. The trace package sets up an *autoload* property to point to */usr/lib/lisp/trace*.

### 10.6. Interrupt processing

The UNIX operating system provides one user interrupt character which defaults to ^C.<sup>†</sup> The user may select a lisp function to run when an interrupt occurs. Since this interrupt could occur at any time, and in particular could occur at a time when the internal stack pointers were in an inconsistent state, the processing of the interrupt may be delayed until a safe time. When the first ^C is typed, the lisp system sets a flag that an interrupt has been requested. This flag is checked at safe places within the interpreter and in the *qlinker* function. If the lisp system doesn't respond to the first ^C, another ^C should be typed. This will cause all of the transfer tables to be cleared forcing all calls from compiled code to go through the *qlinker* function where the interrupt flag will be checked. If the lisp system still doesn't respond, a third ^C will cause an immediate interrupt. This interrupt will not necessarily be in a safe place so the user should *reset* the lisp system as soon as possible.

---

<sup>†</sup>Actually there are two but the lisp system does not allow you to catch the QUIT interrupt.

## CHAPTER 11

### The Joseph Lister Trace Package

The Joseph Lister<sup>†</sup> Trace package is an important tool for the interactive debugging of a Lisp program. It allows you to examine selected calls to a function or functions, and optionally to stop execution of the Lisp program to examine the values of variables.

The trace package is a set of Lisp programs located in the Lisp program library (usually in the file `/usr/lib/lisp/trace.l`). Although not normally loaded in the Lisp system, the package will be loaded in when the first call to `trace` is made.

**(trace** [`ls_arg1` ...])

WHERE: the form of the `ls_argi` is described below.

RETURNS: a list of the function successfully modified for tracing. If no arguments are given to `trace`, a list of all functions currently being traced is returned.

SIDE EFFECT: The function definitions of the functions to trace are modified.

The `ls_argi` can have one of the following forms:

**foo** - when `foo` is entered and exited, the trace information will be printed.

**(foo break)** - when `foo` is entered and exited the trace information will be printed. Also, just after the trace information for `foo` is printed upon entry, you will be put in a special break loop. The prompt is 'T>' and you may type any Lisp expression, and see its value printed. The *i*th argument to the function just called can be accessed as (`arg i`). To leave the trace loop, just type `^D` or (`tracereturn`) and execution will continue. Note that `^D` will work only on UNIX systems.

**(foo if expression)** - when `foo` is entered and the expression evaluates to non-nil, then the trace information will be printed for both exit and entry. If expression evaluates to nil, then no trace information will be printed.

**(foo ifnot expression)** - when `foo` is entered and the expression evaluates to nil, then the trace information will be printed for both entry and exit. If both **if** and **ifnot** are specified, then the **if** expression must evaluate to non nil AND the **ifnot** expression must evaluate to nil for the trace information to be printed out.

**(foo evalin expression)** - when `foo` is entered and after the entry trace information is printed, expression will be evaluated. Exit trace information will be printed when `foo` exits.

---

<sup>†</sup>*Lister, Joseph* 1st Baron Lister of Lyme Regis, 1827-1912; English surgeon: introduced antiseptic surgery.

**(foo evalout expression)** - when foo is entered, entry trace information will be printed. When foo exits, and before the exit trace information is printed, expression will be evaluated.

**(foo evalinout expression)** - this has the same effect as (trace (foo evalin expression evalout expression)).

**(foo lprint)** - this tells *trace* to use the level printer when printing the arguments to and the result of a call to foo. The level printer prints only the top levels of list structure. Any structure below three levels is printed as a &. This allows you to trace functions with massive arguments or results.

The following trace options permit one to have greater control over each action which takes place when a function is traced. These options are only meant to be used by people who need special hooks into the trace package. Most people should skip reading this section.

**(foo tracecenter tefunc)** - this tells *trace* that the function to be called when foo is entered is tefunc. tefunc should be a lambda of two arguments, the first argument will be bound to the name of the function being traced, foo in this case. The second argument will be bound to the list of arguments to which foo should be applied. The function tefunc should print some sort of "entering foo" message. It should not apply foo to the arguments, however. That is done later on.

**(foo traceexit txfunc)** - this tells *trace* that the function to be called when foo is exited is txfunc. txfunc should be a lambda of two arguments, the first argument will be bound to the name of the function being traced, foo in this case. The second argument will be bound to the result of the call to foo. The function txfunc should print some sort of "exiting foo" message.

**(foo evfcn evfunc)** - this tells *trace* that the form evfunc should be evaluated to get the value of foo applied to its arguments. This option is a bit different from the other special options since evfunc will usually be an expression, not just the name of a function, and that expression will be specific to the evaluation of function foo. The argument list to be applied will be available as T-arglist.

**(foo printargs prfunc)** - this tells *trace* to use prfunc to print the arguments to be applied to the function foo. prfunc should be a lambda of one argument. You might want to use this option if you wanted a print function which could handle circular lists. This option will work only if you do not specify your own **tracecenter** function. Specifying the option **lprint** is just a simple way of changing the printargs function to the level printer.

**(foo printres prfunc)** - this tells *trace* to use prfunc to print the result of evaluating foo. prfunc should be a lambda of one argument. This option will work only if you do not specify your own **traceexit** function. Specifying the option **lprint** changes printres to the level printer.

You may specify more than one option for each function traced. For example:

```
(trace (foo if (eq 3 (arg 1)) break lprint) (bar evalin (print xyzzy)))
```

This tells *trace* to trace two more functions, *foo* and *bar*. Should *foo* be called with the first argument *eq* to 3, then the entering *foo* message will be printed with the level printer. Next it will enter a trace break loop, allowing you to evaluate any lisp expressions. When you exit the trace break loop, *foo* will be applied to its arguments and the resulting value will be printed, again using the level printer. *Bar* is also traced, and each time *bar* is entered, an entering *bar* message will be printed and then the value of *xyzy* will be printed. Next *bar* will be applied to its arguments and the result will be printed. If you tell *trace* to trace a function which is already traced, it will first *untrace* it. Thus if you want to specify more than one trace option for a function, you must do it all at once. The following is *not* equivalent to the preceding call to *trace* for *foo*:

```
(trace (foo if (eq 3 (arg 1))) (foo break) (foo lprint))
```

In this example, only the last option, *lprint*, will be in effect.

If the symbol *\$stracemute* is given a non nil value, printing of the function name and arguments on entry and exit will be suppressed. This is particularly useful if the function you are tracing fails after many calls to it. In this case you would tell *trace* to trace the function, set *\$stracemute* to *t*, and begin the computation. When an error occurs you can use *tracedump* to print out the current trace frames.

Generally the trace package has its own internal names for the the lisp functions it uses, so that you can feel free to trace system functions like *cond* and not worry about adverse interaction with the actions of the trace package. You can trace any type of function: *lambda*, *nlambda*, *lexpr* or *macro* whether compiled or interpreted and you can even trace array references (however you should not attempt to store in an array which has been traced).

When tracing compiled code keep in mind that many function calls are translated directly to machine language or other equivalent function calls. A full list of open coded functions is listed at the beginning of the *liszt* compiler source. *Trace* will do a (*sstatus translink nil*) to insure that the new traced definitions it defines are called instead of the old untraced ones. You may notice that compiled code will run slower after this is done.

**(traceargs s\_func [x\_level])**

WHERE: if *x\_level* is missing it is assumed to be 1.

RETURNS: the arguments to the *x\_levelth* call to traced function *s\_func* are returned.

**(tracedump)**

SIDE EFFECT: the currently active trace frames are printed on the terminal. returns a list of functions untraced.

**(untrace [s\_arg1 ...])**

RETURNS: a list of the functions which were untraced.

NOTE: if no arguments are given, all functions are untraced.

SIDE EFFECT: the old function definitions of all traced functions are restored except in the case where it appears that the current definition of a function was not created by trace.

## CHAPTER 12

### Liszt - the lisp compiler

#### 12.1. General strategy of the compiler

The purpose of the lisp compiler, Liszt, is to create an object module which when brought into the lisp system using *fasl* will have the same effect as bringing in the corresponding lisp coded source module with *load* with one important exception, functions will be defined as sequences of machine language instructions, instead of lisp S-expressions. Liszt is not a function compiler, it is a *file* compiler. Such a file can contain more than function definitions; it can contain other lisp S-expressions which are evaluated at load time. These other S-expressions will also be stored in the object module produced by Liszt and will be evaluated at *fasl* time.

As is almost universally true of Lisp compilers, the main pass of Liszt is written in Lisp. A subsequent pass is the assembler, for which we use the standard UNIX assembler.

#### 12.2. Running the compiler

The compiler is normally run in this manner:

**% liszt foo**

will compile the file *foo.l* or *foo* (the preferred way to indicate a lisp source file is to end the file name with '.l'). The result of the compilation will be placed in the file *foo.o* if no fatal errors were detected. All messages which Liszt generates go to the standard output. Normally each function name is printed before it is compiled (the `-q` option suppresses this).

#### 12.3. Special forms

Liszt makes one pass over the source file. It processes each form in this way:

##### 12.3.1. macro expansion

If the form is a macro invocation (i.e it is a list whose *car* is a symbol whose function binding is a macro), then that macro invocation is expanded. This is repeated until the top level form is not a macro invocation. When Liszt begins, there are already some macros defined, in fact some functions (such as *defun*) are actually macros. The user may define his own macros as well. For a macro to be used it must be defined in the Lisp system in which Liszt runs.

##### 12.3.2. classification

After all macro expansion is done, the form is classified according to its *car* (if the form is not a list, then it is classified as an *other*).

**12.3.2.1. eval-when**

The form of `eval-when` is `(eval-when (time1 time2 ...) form1 form2 ...)` where the `timei` are one of `eval`, `compile`, or `load`. The compiler examines the `formi` in sequence and the action taken depends on what is in the time list. If `compile` is in the list then the compiler will invoke `eval` on each `formi` as it examines it. If `load` is in the list then the compiler will recursively call itself to compile each `formi` as it examines it. Note that if `compile` and `load` are in the time list, then the compiler will both evaluate and compile each form. This is useful if you need a function to be defined in the compiler at both compile time (perhaps to aid macro expansion) and at run time (after the file is *fasl*ed in).

**12.3.2.2. declare**

`declare` is used to provide information about functions and variables to the compiler. It is (almost) equivalent to `(eval-when (compile) ...)`. You may declare functions to be one of three types: `lambda` (`*expr`), `nlambda` (`*fexpr`), `lexpr` (`*lexpr`). The names in parenthesis are the Maclisp names and are accepted by the compiler as well (and not just when the compiler is in Maclisp mode). Functions are assumed to be lambdas until they are declared otherwise or are defined differently. The compiler treats calls to lambdas and `lexprs` equivalently, so you needn't worry about declaring `lexprs` either. It is important to declare `nlambdas` or define them before calling them. Another attribute you can declare for a function is `localf` which makes the function 'local'. A local function's name is known only to the functions defined within the file itself. The advantage of a local function is that it can be entered and exited very quickly and it can have the same name as a function in another file and there will be no name conflict.

Variables may be declared special or unspecial. When a special variable is `lambda` bound (either in a `lambda`, `prog` or `do` expression), its old value is stored away on a stack for the duration of the `lambda`, `prog` or `do` expression. This takes time and is often not necessary. Therefore the default classification for variables is unspecial. Space for unspecial variables is dynamically allocated on a stack. An unspecial variable can only be accessed from within the function where it is created by its presence in a `lambda`, `prog` or `do` expression variable list. It is possible to declare that all variables are special as will be shown below.

You may declare any number of things in each `declare` statement. A sample declaration is

```
(declare
  (lambda func1 func2)
  (*fexpr func3)
  (*lexpr func4)
  (localf func5)
  (special var1 var2 var3)
  (unspecial var4))
```

You may also declare all variables to be special with `(declare (specials t))`. You may declare that macro definitions should be compiled as well as evaluated at compile time by `(declare (macros t))`. In fact, as was mentioned above, `declare` is much like `(eval-when (compile) ...)`. Thus if the compiler sees `(declare (foo bar))` and `foo` is defined, then it will evaluate `(foo bar)`. If `foo` is not defined then an undefined `declare` attribute warning will be issued.

**12.3.2.3. (progn 'compile form1 form2 ... formn)**

When the compiler sees this it simply compiles `form1` through `formn` as if they too were seen at top level. One use for this is to allow a macro at top-level to expand into more

than one function definition for the compiler to compile.

#### 12.3.2.4. **include/includef**

*Include* and *includef* cause another file to be read and compiled by the compiler. The result is the same as if the included file were textually inserted into the original file. The only difference between *include* and *includef* is that *include* doesn't evaluate its argument and *includef* does. Nested includes are allowed.

#### 12.3.2.5. **def**

A *def* form is used to define a function. The macros *defun* and *defmacro* expand to a *def* form. If the function being defined is a lambda, *nlambda* or *lexpr* then the compiler converts the lisp definition to a sequence of machine language instructions. If the function being defined is a macro, then the compiler will evaluate the definition, thus defining the macro withing the running Lisp compiler. Furthermore, if the variable *macros* is set to a non nil value, then the macro definition will also be translated to machine language and thus will be defined when the object file is fasled in. The variable *macros* is set to t by (*declare (macros t)*).

When a function or macro definition is compiled, macro expansion is done whenever possible. If the compiler can determine that a form would be evaluated if this function were interpreted then it will macro expand it. It will not macro expand arguments to a *nlambda* unless the characteristics of the *nlambda* is known (as is the case with *cond*). The map functions (*map*, *mapc*, *mapcar*, and so on) are expanded to a *do* statement. This allows the first argument to the map function to be a lambda expression which references local variables of the function being defined.

#### 12.3.2.6. **other forms**

All other forms are simply stored in the object file and are evaluated when the file is *fasled* in.

### 12.4. Using the compiler

The previous section describes exactly what the compiler does with its input. Generally you won't have to worry about all that detail as files which work interpreted will work compiled. Following is a list of steps you should follow to insure that a file will compile correctly.

- [1] Make sure all macro definitions precede their use in functions or other macro definitions. If you want the macros to be around when you *fasl* in the object file you should include this statement at the beginning of the file: (*declare (macros t)*)
- [2] Make sure all *nlambdas* are defined or declared before they are used. If the compiler comes across a call to a function which has not been defined in the current file, which does not currently have a function binding, and whose type has not been declared then it will assume that the function needs its arguments evaluated (i.e. it is a lambda or *lexpr*) and will generate code accordingly. This means that you do not have to declare *nlambda* functions like *status* since they have an *nlambda* function binding.
- [3] Locate all variables which are used for communicating values between functions. These variables must be declared special at the beginning of a file. In most cases there won't be many special declarations but if you fail to declare a variable special that should be, the

compiled code could fail in mysterious ways. Let's look at a common problem, assume that a file contains just these three lines:

```
(def aaa (lambda (glob loc) (bbb loc)))
(def bbb (lambda (myloc) (add glob myloc)))
(def ccc (lambda (glob loc) (bbb loc)))
```

We can see that if we load in these two definitions then `(aaa 3 4)` is the same as `(add 3 4)` and will give us 7. Suppose we compile the file containing these definitions. When Liszt compiles `aaa`, it will assume that both `glob` and `loc` are local variables and will allocate space on the temporary stack for their values when `aaa` is called. Thus the values of the local variables `glob` and `loc` will not affect the values of the symbols `glob` and `loc` in the Lisp system. Now Liszt moves on to function `bbb`. `Myloc` is assumed to be local. When it sees the `add` statement, it finds a reference to a variable called `glob`. This variable is not a local variable to this function and therefore `glob` must refer to the value of the symbol `glob`. Liszt will automatically declare `glob` to be special and it will print a warning to that effect. Thus subsequent uses of `glob` will always refer to the symbol `glob`. Next Liszt compiles `ccc` and treats `glob` as a special and `loc` as a local. When the object file is *fasl'*ed in, and `(ccc 3 4)` is evaluated, the symbol `glob` will be lambda bound to 3 `bbb` will be called and will return 7. However `(aaa 3 4)` will fail since when `bbb` is called, `glob` will be unbound. What should be done here is to put `(declare (special glob))` at the beginning of the file.

- [4] Make sure that all calls to *arg* are within the *lexpr* whose arguments they reference. If *foo* is a compiled *lexpr* and it calls *bar* then *bar* cannot use *arg* to get at *foo*'s arguments. If both *foo* and *bar* are interpreted this will work however. The macro *listify* can be used to put all of some of a *lexpr*'s arguments in a list which then can be passed to other functions.

## 12.5. Compiler options

The compiler recognizes a number of options which are described below. The options are typed anywhere on the command line preceded by a minus sign. The entire command line is scanned and all options recorded before any action is taken. Thus

```
% liszt -mx foo
% liszt -m -x foo
% liszt foo -mx
```

are all equivalent. Before scanning the command line for options, `liszt` looks for in the environment for the variable `LISZT`, and if found scans its value as if it was a string of options. The meaning of the options are:

- C** The assembler language output of the compiler is commented. This is useful when debugging the compiler and is not normally done since it slows down compilation.
- I** The next command line argument is taken as a filename, and loaded prior to compilation.
- e** Evaluate the next argument on the command line before starting compilation. For example `% liszt -e '(setq foobar "foo string")' foo` will evaluate the above s-expression. Note that the shell requires that the arguments be surrounded by single quotes.
- i** Compile this program in interlisp compatibility mode. This is not implemented yet.
- m** Compile this program in Maclisp mode. The reader syntax will be changed to the Maclisp syntax and a file of macro definitions will be loaded in (usually named `/usr/lib/lisp/machacks`). This switch brings us sufficiently close to Maclisp to allow us to compile `Macsyma`, a large Maclisp program. However Maclisp is a moving target and we can't guarantee that this switch will allow you to compile any given program.

- o Select a different object or assembler language file name. For example  

```
% liszt foo -o xxx.o
```

will compile foo and into xxx.o instead of the default foo.o, and  

```
% liszt bar -S -o xxx.s
```

will compile to assembler language into xxx.s instead of bar.s.
- p place profiling code at the beginning of each non-local function. If the lisp system is also created with profiling in it, this allows function calling frequency to be determined (see *prof(1)*)
- q Run in quiet mode. The names of functions being compiled and various "Note"'s are not printed.
- Q print compilation statistics and warn of strange constructs. This is the inverse of the **q** switch and is the default.
- r place bootstrap code at the beginning of the object file, which when the object file is executed will cause a lisp system to be invoked and the object file *fasted* in. This is known as 'autorun' and is described below.
- S Create an assembler language file only.  

```
% liszt -S foo
```

will create the file assembler language file foo.s and will not attempt to assemble it. If this option is not specified, the assembler language file will be put in the temporary disk area under a automatically generated name based on the lisp compiler's process id. Then if there are no compilation errors, the assembler will be invoked to assemble the file.
- T Print the assembler language output on the standard output file. This is useful when debugging the compiler.
- u Run in UCI-Lisp mode. The character syntax is changed to that of UCI-Lisp and a UCI-Lisp compatibility package of macros is read in.
- w Suppress warning messages.
- x Create an cross reference file.  

```
% liszt -x foo
```

not only compiles foo into foo.o but also generates the file foo.x . The file foo.x is lisp readable and lists for each function all functions which that function could call. The program *lxref* reads one or more of these ".x" files and produces a human readable cross reference listing.

## 12.6. autorun

The object file which *liszt* writes does not contain all the functions necessary to run the lisp program which was compiled. In order to use the object file, a lisp system must be started and the object file *fasted* in. When the **-r** switch is given to *liszt*, the object file created will contain a small piece of bootstrap code at the beginning, and the object file will be made executable. Now, when the name of the object file is given to the UNIX command interpreter (shell) to run, the bootstrap code at the beginning of the object file will cause a lisp system to be started and the first action the lisp system will take is to *fast* in the object file which started it. In effect the object file has created an environment in which it can run.

Autorun is an alternative to *dumplisp*. The advantage of autorun is that the object file which starts the whole process is typically small, whereas the minimum *dumplisped* file is very large (one half megabyte). The disadvantage of autorun is that the file must be *fasted* into a lisp each time it is used whereas the file which *dumplisp* creates can be run as is. *liszt* itself is a *dumplisped* file since it is used so often and is large enough that too much time would be wasted *fasting* it in each time it was used. The lisp cross reference program, *lxref*, uses *autorun* since it is a small and rarely used program.

In order to have the program *fasled* in begin execution (rather than starting a lisp top level), the value of the symbol `user-top-level` should be set to the name of the function to get control. An example of this is shown next.

---

*we want to replace the unix date program with one written in lisp.*

```
% cat lispdate.l
(defun mydate nil
  (patom "The date is ")
  (patom (status ctime))
  (terpr)
  (exit 0))
(setq user-top-level 'mydate)

% liszt -r lispdate
Compilation begins with Lisp Compiler 5.2
source: lispdate.l, result: lispdate.o
mydate
%Note: lispdate.l: Compilation complete
%Note: lispdate.l: Time: Real: 0:3, CPU: 0:0.28, GC: 0:0.00 for 0 gcs
%Note: lispdate.l: Assembly begins
%Note: lispdate.l: Assembly completed successfully
3.0u 2.0s 0:17 29%
```

*We change the name to remove the ".o", (this isn't necessary)*

```
% mv lispdate.o lispdate
```

*Now we test it out*

```
% lispdate
The date is Sat Aug 1 16:58:33 1981
%
```

---

## 12.7. pure literals

Normally the quoted lisp objects (literals) which appear in functions are treated as constants. Consider this function:

```
(def foo
  (lambda nil (cond ((not (eq 'a (car (setq x '(a b)))))
                    (print 'impossible!!))
                    (t (rplaca x 'd)))))
```

At first glance it seems that the first `cond` clause will never be true, since the `car` of `(a b)` should always be `a`. However if you run this function twice, it will print `'impossible!!'` the second time. This is because the following clause modifies the 'constant' list `(a b)` with the `rplaca` function. Such modification of literal lisp objects can cause programs to behave strangely as the above example shows, but more importantly it can cause garbage collection problems if done to compiled code. When a file is *fasled* in, if the symbol `$purcopylits` is non nil, the literal lisp data is put in 'pure' space, that is it put in space which needn't be looked at by the garbage collector. This reduces the work the garbage collector must do but it is dangerous since if the literals are modified to point to non pure objects, the marker may not mark the non pure objects. If the symbol `$purcopylits` is nil then the literal lisp data is put in impure space and the compiled code will act like the interpreted code when literal data is modified. The default value for `$purcopylits` is `t`.

## 12.8. transfer tables

A transfer table is setup by *fasl* when the object file is loaded in. There is one entry in the transfer table for each function which is called in that object file. The entry for a call to the function *foo* has two parts whose contents are:

- [1] function address □ This will initially point to the internal function *qlinker*. It may some time in the future point to the function *foo* if certain conditions are satisfied (more on this below).
- [2] function name □ This is a pointer to the symbol *foo*. This will be used by *qlinker*.

When a call is made to the function *foo* the call will actually be made to the address in the transfer table entry and will end up in the *qlinker* function. *Qlinker* will determine that *foo* was the function being called by locating the function name entry in the transfer table<sup>†</sup>. If the function being called is not compiled then *qlinker* just calls *funcall* to perform the function call. If *foo* is compiled and if (*status translink*) is non nil, then *qlinker* will modify the function address part of the transfer table to point directly to the function *foo*. Finally *qlinker* will call *foo* directly. The next time a call is made to *foo* the call will go directly to *foo* and not through *qlinker*. This will result in a substantial speedup in compiled code to compiled code transfers. A disadvantage is that no debugging information is left on the stack, so *showstack* and *backtrace* are useless. Another disadvantage is that if you redefine a compiled function either through loading in a new version or interactively defining it, then the old version may still be called from compiled code if the fast linking described above has already been done. The solution to these problems is to use (*status translink value*). If value is

- nil* All transfer tables will be cleared, i.e. all function addresses will be set to point to *qlinker*. This means that the next time a function is called *qlinker* will be called and will look at the current definition. Also, no fast links will be set up since (*status translink*) will be nil. The end result is that *showstack* and *backtrace* will work and the function definition at the time of call will always be used.
- on* This causes the lisp system to go through all transfer tables and set up fast links wherever possible. This is normally used after you have *fasled* in all of your files. Furthermore since (*status translink*) is not nil, *qlinker* will make new fast links if the situation arises (which isn't likely unless you *fasl* in another file).
- t* This or any other value not previously mentioned will just make (*status translink*) be non nil, and as a result fast links will be made by *qlinker* if the called function is compiled.

## 12.9. Fixnum functions

The compiler will generate inline arithmetic code for fixnum only functions. Such functions include +, -, \*, /, \, 1+ and 1-. The code generated will be much faster than using *add*, *difference*, etc. However it will only work if the arguments to and results of the functions are fixnums. No type checking is done.

---

<sup>†</sup>*Qlinker* does this by tracing back the call stack until it finds the *calls* machine instruction which called it. The address field of the *calls* contains the address of the transfer table entry.

## CHAPTER 13

### The CMU User Toplevel and the File Package

This documentation was written by Don Cohen, and the functions described below were imported from PDP-10 CMULisp.

*Non CMU users note:* this is not the default top level for your Lisp system. In order to start up this top level, you should type (*load 'cmuenv*).

#### 13.1. User Command Input Top Level

The top-level is the function that reads what you type, evaluates it and prints the result. The *newlisp* top-level was inspired by the CMULisp top-level (which was inspired by *interlisp*) but is much simpler. The top-level is a function (of zero arguments) that can be called by your program. If you prefer another top-level, just redefine the top-level function and type "(reset)" to start running it. The current top-level simply calls the functions *tread*, *tlevel* and *tlprint* to read, evaluate and print. These are supposed to be replaceable by the user. The only one that would make sense to replace is *tlprint*, which currently uses a function that refuses to go below a certain level and prints "...]" when it finds itself printing a circular list. One might want to *prettyprint* the results instead. The current top-level numbers the lines that you type to it, and remembers the last *n* "events" (where *n* can be set but is defaulted to 25). One can refer to these events in the following "top-level commands":

---

#### TOPELVEL COMMAND SUMMARY

??	prints events - both the input and the result. If you just type "??" you will see all of the recorded events. "?? 3" will show only event 3, and "?? 3 6" will show events 3 through 6.
redo	pretends that you typed the same thing that was typed before. If you type "redo 3" event number 3 is redone. "redo -3" redoes the thing 3 events ago. "redo" is the same as "redo -1".
ed	calls the editor and then does whatever the editor returns. Thus if you want to do event 5 again except for some small change, you can type "ed 5", make the change and leave the editor. "ed -3" and "ed" are analogous to redo.

---

Finally, you can get the value of event 7 with the function (*valueof* 7). The other interesting feature of the top-level is that it makes outermost parentheses superfluous for the most part. This works the same way as in CMULisp, so you can use the help for an explanation. If you're not sure and don't want to risk it you can always just include the parentheses.

**(top-level)**

SIDE EFFECT: *top-level* is the LISP top level function. As well as being the top level function with which the user interacts, it can be called recursively by the user or any function. Thus, the top level can be invoked from inside the editor, break package, or a user function to make its commands available to the user.

NOTE: The CMU FRANZ LISP top-level uses *lineread* rather than *read*. The difference will not usually be noticeable. The principal thing to be careful about is that input to the function or system being called cannot appear on the same line as the top-level call. For example, typing *(editf foo)P* on one line will edit *foo* and evaluate *P*, not edit *foo* and execute the *p* command in the editor. *top-level* specially recognizes the following commands:

**(valueof 'g\_eventspec)**

RETURNS: the value(s) of the event(s) specified by *g\_eventspec*. If a single event is specified, its value will be returned. If more than one event is specified, or an event has more than one subevent (as for *redo*, etc), a list of values will be returned.

**13.2. The File Package**

Users typically define functions in lisp and then want to save them for the next session. If you do (*changes*), a list of the functions that are newly defined or changed will be printed. When you type (*dskouts*), the functions associated with files will be saved in the new versions of those files. In order to associate functions with files you can either add them to the *filefns* list of an existing file or create a new file to hold them. This is done with the *file* function. If you type (*file new*) the system will create a variable called *newfns*. You may add the names of the functions to go into that file to *newfns*. After you do (*changes*), the functions which are in no other file are stored in the value of the atom *changes*. To put these all in the new file, (*setq newfns (append newfns changes)*). Now if you do (*changes*), all of the changed functions should be associated with files. In order to save the changes on the files, do (*dskouts*). All of the changed files (such as NEW) will be written. To recover the new functions the next time you run FRANZ LISP, do (*dskin new*).

---

**(changes s\_flag)**

RETURNS: Changes computes a list containing an entry for each file which defines atoms that have been marked changed. The entry contains the file name and the changed atoms defined therein. There is also a special entry for changes to atoms which are not defined in any known file. The global variable *filelst* contains the list of "known" files. If no flag is passed this result is printed in human readable form and the value returned is t if there were any changes and nil if not. Otherwise nothing is printed and the computer list is returned. The global variable *changes* contains the atoms which are marked changed but not yet associated with any file. The *changes* function attempts to associate these names with files, and any that are not found are considered to belong to no file. The *changes* property is the means by which changed functions are associated with files. When a file is read in or written out its *changes* property is removed.

**(dc s\_word s\_id [ g\_descriptor1 ... ] <text> <esc>)**

RETURNS: *dc* defines comments. It is exceptional in that its behavior is very context dependent. When *dc* is executed from *dskin* it simply records the fact that the comment exists. It is expected that in interactive mode comments will be found via *getdef* - this allows large comments which do not take up space in your core image. When *dc* is executed from the terminal it expects you to type a comment. *dskout* will write out the comments that you define and also copy the comments on the old version of the file, so that the new version will keep the old comments even though they were never actually brought into core. The optional id is a mechanism for distinguishing among several comments associated with the same word. It defaults to nil. However if you define two comments with the same id, the second is considered to be a replacement for the first. The behavior of *dc* is determined by the value of the global variable *def-comment*. *def-comment* contains the name of a function that is run. Its arguments are the word, id and attribute list. *def-comment* is initially *dc-defline*. Other functions rebind it to *dc-help*, *dc-userhelp*, and the value of

*dskin-comment*. The comment property of an atom is a list of entries, each representing one comment. Atomic entries are assumed to be identifiers of comments on a file but not in core. In-core comments are represented by a list of the id, the attribute list and the comment text. The comment text is an uninterned atom. Comments may be deleted or reordered by editing the comment property.

**(*dskin* l\_filenames)**

SIDE EFFECT: READ-EVAL-PRINTs the contents of the given files. This is the function to use to read files created by *dskout*. *dskin* also declares the files that it reads (if a *file-fns* list is defined and the file is otherwise declarable by *file* ), so that changes to it can be recorded.

**(*dskout* s\_file1 ...)**

SIDE EFFECT: For each file specified, *dskout* assumes the list named filenameFNS (i.e., the file name, excluding extension, concatenated with *fns* ) contains a list of function names, etc., to be loaded Any previous version of the file will be renamed to have extension ".back".

**(*dskouts* s\_file1 ...)**

SIDE EFFECT: applies *dskout* to and prints the name of each *s\_filei* (with no additional arguments, assuming filenameFNS to be a list to be loaded) for which *s\_filei* is either not in *filelst* (meaning it is a new file not previously declared by *file* or given as an argument to *dskin*, *dskouts*, or *dskouts*) or is in *filelst* and has some recorded changes to definitions of atoms in filenameFNS, as recorded by *mark!changed* and noted by *changes*. If *filei* is not specified, *filelst* will be used. This is the most common way of using *dskouts*. Typing (*dskouts*) will save every file reported by (*changes*) to have changed definitions.

**(*dv* s\_atom g\_value)**

EQUIVALENT TO: (*setq atom 'value*). *dv* calls *mark!changed*.

**(*file* 's\_file)**

SIDE EFFECT: declares its argument to be a file to be used for reporting and saving changes to functions by adding the file name to a list of files, *filelst*. *file* is called for each file argument of *dskin*, *dskout*, and *dskouts*.

**(*file-fns* 's\_file)**

RETURNS: the name of the fileFNS list for its file argument *s\_file*.

**(*getdef* 's\_file ['s\_i1 ...])**

SIDE EFFECT: selectively executes definitions for atoms *s\_i1* ... from the specified file. Any of the words to be defined which end with "@" will be treated as patterns in which the @ matches any suffix (just like the editor). *getdef* is driven by *getdefable* (and thus may be programmed). It looks for lines in the file that start with a word in the table. The first character must be "(" or "[" followed by the word, followed by a space, return or something else that will not be considered as part of the identifier by *read*, e.g., "(" is unacceptable. When one is found the next word is read. If it matches one of the identifiers in the call to *getdef* then the table entry is executed. The table entry is a function of the expression starting in this line. Output from *dskout* is in acceptable format for *getdef*. *getdef*

RETURNS: a list of the words which match the ones it looked for, for which it found (but, depending on the table, perhaps did not execute) in the file.

NOTE: *getdeftable* is the table that drives *getdef*. It is in the form of an association list. Each element is a dotted pair consisting of the name of a function for which *getdef* searches and a function of one argument to be executed when it is found.

**(mark!changed 's\_f)**

SIDE EFFECT: records the fact that the definition of *s\_f* has been changed. It is automatically called by *def*, *defun*, *de*, *df*, *defprop*, *dm*, *dv*, and the editor when a definition is altered.

## CHAPTER 14

### The LISP Stepper

#### 14.1. Simple Use Of Stepping

(**step** s\_arg1...)

NOTE: The LISP "stepping" package is intended to give the LISP programmer a facility analogous to the Instruction Step mode of running a machine language program. The user interface is through the function (fexpr) *step*, which sets switches to put the LISP interpreter in and out of "stepping" mode. The most common *step* invocations follow. These invocations are usually typed at the top-level, and will take effect immediately (i.e. the next S-expression typed in will be evaluated in stepping mode).

---

```
(step t)                ; Turn on stepping mode.  
(step nil)             ; Turn off stepping mode.
```

---

SIDE EFFECT: In stepping mode, the LISP evaluator will print out each S-exp to be evaluated before evaluation, and the returned value after evaluation, calling itself recursively to display the stepped evaluation of each argument, if the S-exp is a function call. In stepping mode, the evaluator will wait after displaying each S-exp before evaluation for a command character from the console.

---

*STEP COMMAND SUMMARY*

<return>	Continue stepping recursively.
c	Show returned value from this level only, and continue stepping upward.
e	Only step interpreted code.
g	Turn off stepping mode. (but continue evaluation without stepping).
n <number>	Step through <number> evaluations without stopping
p	Redisplay current form in full (i.e. rebind prinlevel and prinlength to nil)
b	Get breakpoint
q	Quit
d	Call debug

---

## 14.2. Advanced Features

### 14.2.1. Selectively Turning On Stepping.

If  
*(step foo1 foo2 ...)*

is typed at top level, stepping will not commence immediately, but rather when the evaluator first encounters an S-expression whose car is one of *foo1*, *foo2*, etc. This form will then display at the console, and the evaluator will be in stepping mode waiting for a command character.

Normally the stepper intercepts calls to *funcall* and *eval*. When *funcall* is intercepted, the arguments to the function have already been evaluated but when *eval* is intercepted, the arguments have not been evaluated. To differentiate the two cases, when printing the form in evaluation, the stepper preceded intercepted calls to *funcall* with "f:". Calls to *funcall* are normally caused by compiled lisp code calling other functions, whereas calls to *eval* usually occur when lisp code is interpreted. To step only calls to eval use: *(step e)*

### 14.2.2. Stepping With Breakpoints.

For the moment, step is turned off inside of error breaks, but not by the break function. Upon exiting the error, step is reenabled. However, executing *(step nil)* inside a error loop will turn off stepping globally, i.e. within the error loop, and after return has been made from the loop.

### 14.3. Overhead of Stepping.

If stepping mode has been turned off by (*step nil*), the execution overhead of having the stepping packing in your LISP is identically nil. If one stops stepping by typing "g", every call to *eval* incurs a small overhead--several machine instructions, corresponding to the compiled code for a simple *cond* and one function pushdown. Running with (*step foo1 foo2 ...*) can be more expensive, since a member of the *car* of the current form into the list (*foo1 foo2 ...*) is required at each call to *eval*.

### 14.4. Evalhook and Funcallhook

There are hooks in the FRANZ LISP interpreter to permit a user written function to gain control of the evaluation process. These hooks are used by the Step package just described. There are two hooks and they have been strategically placed in the two key functions in the interpreter: *eval* (which all interpreted code goes through) and *funcall* (which all compiled code goes through if (*sstatus translink nil*) has been done). The hook in *eval* is compatible with Maclisp, but there is no Maclisp equivalent of the hook in *funcall*.

To arm the hooks two forms must be evaluated: (*\*rset t*) and (*sstatus evalhook t*). Once that is done, *eval* and *funcall* do a special check when they enter.

If *eval* is given a form to evaluate, say (*foo bar*), and the symbol 'evalhook' is non nil, say its value is 'ehook', then *eval* will lambda bind the symbols 'evalhook' and 'funcallhook' to nil and will call ehook passing (*foo bar*) as the argument. It is ehook's responsibility to evaluate (*foo bar*) and return its value. Typically ehook will call the function 'evalhook' to evaluate (*foo bar*). Note that 'evalhook' is a symbol whose function binding is a system function described in Chapter 4, and whose value binding, if non nil, is the name of a user written function (or a lambda expression, or a binary object) which will gain control whenever *eval* is called. 'evalhook' is also the name of the *status* tag which must be set for all of this to work.

If *funcall* is given a function, say *foo*, and a set of already evaluated arguments, say *barv* and *bazv*, and if the symbol 'funcallhook' has a non nil value, say 'fhook', then *funcall* will lambda bind 'evalhook' and 'funcallhook' to nil and will call fhook with arguments *barv*, *bazv* and *foo*. Thus fhook must be a *lexpr* since it may be given any number of arguments. The function to call, *foo* in this case, will be the *last* of the arguments given to fhook. It is fhook's responsibility to do the function call and return the value. Typically fhook will call the function *funcallhook* to do the *funcall*. This is an example of a *funcallhook* function which just prints the arguments on each entry to *funcall* and the return value.

---

```

-> (defun fhook n (let ((form (cons (arg n) (listify (1- n))))
                    (retval)
                    (patom "calling ")(print form)(terpr)
                    (setq retval (funcallhook form 'fhook))
                    (patom "returns ")(print retval)(terpr)
                    retval))

fhook
-> (*rset t) (sstatus evalhook t) (sstatus translink nil)
-> (setq funcallhook 'fhook)
calling (print fhook)           ;; now all compiled code is traced
fhookreturns nil
calling (terpr)

returns nil
calling (patom "-> ")
-> returns "-> "
calling (read nil Q00000)
(array foo t 10)                ;; to test it, we see what happens when
returns (array foo t 10)        ;; we make an array
calling (eval (array foo t 10))
calling (append (10) nil)
returns (10)
calling (lessp 1 1)
returns nil
calling (apply times (10))
returns 10
calling (small-segment value 10)
calling (boole 4 137 127)
returns 128
... there is plenty more ...

```

---

## CHAPTER 15

### The FIXIT Debugger

**15.1. Introduction** FIXIT is a debugging environment for FRANZ LISP users doing program development. This documentation and FIXIT were written by David S. Touretzky of Carnegie-Mellon University for MACLisp, and adapted to FRANZ LISP by Mitch Marcus of Bell Labs. One of FIXIT's goals is to get the program running again as quickly as possible. The user is assisted in making changes to his functions "on the fly", i.e. in the midst of execution, and then computation is resumed.

To enter the debugger type (*debug*). The debugger goes into its own read-eval-print loop. Like the top-level, the debugger understands certain special commands. One of these is *help*, which prints a list of the available commands. The basic idea is that you are somewhere in a stack of calls to eval. The command "bka" is probably the most appropriate for looking at the stack. There are commands to move up and down. If you want to know the value of "x" as of some place in the stack, move to that place and type "x" (or (cdr x) or anything else that you might want to evaluate). All evaluation is done as of the current stack position. You can fix the problem by changing the values of variables, editing functions or expressions in the stack etc. Then you can continue from the current stack position (or anywhere else) with the "redo" command. Or you can simply return the right answer with the "return" command.

When it is not immediately obvious why an error has occurred or how the program got itself into its current state, FIXIT comes to the rescue by providing a powerful debugging loop in which the user can:

- examine the stack
- evaluate expressions in context
- enter stepping mode
- restart the computation at any point

The result is that program errors can be located and fixed extremely rapidly, and with a minimum of frustration.

The debugger can only work effectively when extra information is kept about forms in evaluation by the lisp system. Evaluating (*\*reset t*) tells the lisp system to maintain this information. If you are debugging compiled code you should also be sure that the compiled code to compiled code linkage tables are unlinked, i.e do (*sstatus translink nil*).

**(debug [ s\_msg ])**

NOTE: Within a program, you may enter a debug loop directly by putting in a call to *debug* where you would normally put a call to *break*. Also, within a break loop you may enter FIXIT by typing *debug*. If an argument is given to DEBUG, it is treated as a message to be printed before the debug loop is entered. Thus you can put (*debug !just before loop!*) into a program to indicate what part of the program is being debugged.

---

*FIXIT Command Summary*

TOP go to top of stack (latest expression)  
 BOT go to bottom of stack (first expression)  
 P show current expression (with ellipsis)  
 PP show current expression in full  
 WHERE give current stack position  
 HELP types the abbreviated command summary found  
 in /usr/lisp/doc/fixit.help. H and ? work too.  
 U go up one stack frame  
 U n go up n stack frames  
 U f go up to the next occurrence of function f  
 U n f go up n occurrences of function f  
 UP go up to the next user-written function  
 UP n go up n user-written functions  
 ...the DN and DNFN commands are similar, but go down  
 ...instead of up.  
 OK resume processing; continue after an error or debug loop  
 REDO restart the computation with the current stack frame.  
 The OK command is equivalent to TOP followed by REDO.  
 REDO f restart the computation with the last call to function f.  
 (The stack is searched downward from the current position.)  
 STEP restart the computation at the current stack frame,  
 but first turn on stepping mode. (Assumes Rich stepper is loaded.)  
 RETURN e return from the current position in the computation  
 with the value of expression e.  
 BK.. print a backtrace. There are many backtrace commands,  
 formed by adding suffixes to the BK command. "BK" gives  
 a backtrace showing only user-written functions, and uses  
 ellipsis. The BK command may be suffixed by one or more  
 of the following modifiers:  
 ..F.. show function names instead of expressions  
 ..A.. show all functions/expressions, not just user-written ones  
 ..V.. show variable bindings as well as functions/expressions  
 ..E.. show everything in the expression, i.e. don't use ellipsis  
 ..C.. go no further than the current position on the stack  
 Some of the more useful combinations are BKFV, BKFA,  
 and BKFAV.  
 BK.. n show only n levels of the stack (starting at the top).  
 (BK n counts only user functions; BKA n counts all functions.)  
 BK.. f show stack down to first call of function f  
 BK.. n f show stack down to nth call of function f

---

**15.2. Interaction with *trace*** FIXIT knows about the standard Franz trace package, and tries to make tracing invisible while in the debug loop. However, because of the way *trace* works, it may sometimes be the case that the functions on the stack are really *uninterned* atoms that have the same name as a traced function. (This only happens when a function is traced WHEREIN another one.) FIXIT will call attention to *trace's* hackery by printing an appropriate tag next to these stack entries.

**15.3. Interaction with *step*** The *step* function may be invoked from within FIXIT via the STEP command. FIXIT initially turns off stepping when the debug loop is entered. If you step through a function and get an error, FIXIT will still be invoked normally. At any time during stepping, you may explicitly enter FIXIT via the "D" (debug) command.

**15.4. Multiple error levels** FIXIT will evaluate arbitrary LISP expressions in its debug loop. The evaluation is not done within an *errset*, so, if an error occurs, another invocation of the debugger can be made. When there are multiple errors on the stack, FIXIT displays a barrier symbol between each level that looks something like <-----UDF-->. The UDF in this case stands for UnDefined Function. Thus, the upper level debug loop was invoked by an undefined function error that occurred while in the lower loop.

## CHAPTER 16

### The LISP Editor

#### 16.1. The Editors

It is quite possible to use VI, Emacs or other standard editors to edit your lisp programs, and many people do just that. However there is a lisp structure editor which is particularly good for the editing of lisp programs, and operates in a rather different fashion, namely within a lisp environment application. It is handy to know how to use it for fixing problems without exiting from the lisp system (e.g. from the debugger so you can continue to execute rather than having to start over.) The editor is not quite like the top-level and debugger, in that it expects you to type editor commands to it. It will not evaluate whatever you happen to type. (There is an editor command to evaluate things, though.)

The editor is available (assuming your system is set up correctly with a lisp library) by typing (load 'cmufncs) and (load 'cmuedit).

The most frequent use of the editor is to change function definitions by starting the editor with one of the commands described in section 16.14. (see *editf*), values (*editv*), properties (*editp*), and expressions (*edite*). The beginner is advised to start with the following (very basic) commands: *ok*, *undo*, *p*, *#*, under which are explained two different basic commands which start with numbers, and *f*.

This documentation, and the editor, were imported from PDP-10 CMULisp by Don Cohen. PDP-10 CMULisp is based on UCILisp, and the editor itself was derived from an early version of Interlisp. Lars Ericson, the author of this section, has provided this very concise summary. Tutorial examples and implementation details may be found in the Interlisp Reference Manual, where a similar editor is described.

#### 16.2. Scope of Attention

Attention-changing commands allow you to look at a different part of a Lisp expression you are editing. The sub-structure upon which the editor's attention is centered is called "the current expression". Changing the current expression means shifting attention and not actually modifying any structure.

---

##### SCOPE OF ATTENTION COMMAND SUMMARY

*n* (*n*>0) . Makes the *n*th element of the current expression be the new current expression.

-*n* (*n*>0). Makes the *n*th element from the end of the current expression be the new current expression.

0. Makes the next higher expression be the new correct expression. If the intention is to go back to the next higher left parenthesis,

use the command !0.

*up* . If a *p* command would cause the editor to type ... before typing the current expression, (the current expression is a tail of the next higher expression) then has no effect; else, *up* makes the old current expression the first element in the new current expression.

*!0* . Goes back to the next higher left parenthesis.

*^* . Makes the top level expression be the current expression.

*nx* . Makes the current expression be the next expression.

(*nx n*) equivalent to *n nx* commands.

*!nx* . Makes current expression be the next expression at a higher level. Goes through any number of right parentheses to get to the next expression.

*bk* . Makes the current expression be the previous expression in the next higher expression.

(*nth n*) *n*>0 . Makes the list starting with the *nth* element of the current expression be the current expression.

(*nth \$*) - *generalized nth command*. *nth* locates *\$*, and then backs up to the current level, where the new current expression is the tail whose first element contains, however deeply, the expression that was the terminus of the location operation.

:: . (pattern :: . \$) e.g., (cond :: return). finds a cond that contains a return, at any depth.

(*below com x*) . The below command is useful for locating a substructure by specifying something it contains. (below cond) will cause the cond clause containing the current expression to become the new current expression. Suppose you are editing a list of lists, and want to find a sublist that contains a foo (at any depth). Then simply executes *f foo* (below).

(*nex x*) . same as (*below x*) followed by *nx*. For example, if you are deep inside of a selectq clause, you can advance to the next clause with (*nex selectq*).

*nex*. The atomic form of *nex* is useful if you will be performing repeated executions of (*nex x*). By simply marking the chain corresponding to *x*, you can use *nex* to step through the sublists.

### 16.3. Pattern Matching Commands

Many editor commands that search take patterns. A pattern *pat* matches with *x* if:

#### PATTERN SPECIFICATION SUMMARY

- *pat* is *eq* to *x*.

- *pat* is *&*.

- *pat* is a number and equal to *x*.

- if (car *pat*) is the atom \*any\*, (cdr *pat*) is a list of patterns, and *pat* matches *x* if and only if one of the patterns on (cdr *pat*) matches *x*.

- if *pat* is a literal atom or string, and (nthchar *pat* -1) is @, then *pat* matches with any literal atom or string which has the same initial characters as *pat*, e.g. ver@ matches with verylongatom, as well as "verylongstring".

- if (car *pat*) is the atom --, *pat* matches *x* if (a) (cdr *pat*)=nil, i.e. *pat*=(--), e.g., (a --) matches (a) (a b c) and (a . b) in other words, -- can match any tail of a list. (b) (cdr *pat*) matches with some tail of *x*, e.g. (a -- (&)) will match with (a b c (d)), but not (a b c d), or (a b c (d) e). however, note that (a -- (& --)) will match with (a b c (d) e). in other words, -- will match any interior segment of a list.

- if (car *pat*) is the atom ==, *pat* matches *x* if and only if (cdr *pat*) is *eq* to *x*. (this pattern is for use by programs that call the editor as a subroutine, since any non-atomic expression in a command typed in by the user obviously cannot be *eq* to existing structure.) - otherwise if *x* is a list, *pat* matches *x* if (car *pat*) matches (car *x*), and (cdr *pat*) matches (cdr *x*).

- when searching, the pattern matching routine is called only to match with elements in the structure, unless the pattern begins with :::, in which case cdr of the pattern is matched against tails in the structure. (in this case, the tail does not have to be a proper tail, e.g. (::: a -) will match with the element (a b c) as well as with cdr of (x a b c), since (a b c) is a tail of (a b c).)

---

### 16.3.1. Commands That Search

---

#### SEARCH COMMAND SUMMARY

*f pattern* . *f* informs the editor that the next command is to be interpreted as a pattern. If no pattern is given on the same line as the *f* then the last pattern is used. *f pattern* means find the next instance of pattern.

*(f pattern n)*. Finds the next instance of pattern.

*(f pattern t)*. similar to *f pattern*, except, for example, if the current expression is (cond .), *f cond* will look for the next cond, but (f cond t) will 'stay here'.

*(f pattern n) n>0*. Finds the *n*th place that pattern matches. If the current expression is (foo1 foo2 foo3), (f f00@ 3) will find foo3.

*(f pattern)* or *(f pattern nil)*. only matches with elements at the top level of the current expression. If the current expression is (prog nil (setq x (cond & &)) (cond & ...) f (cond --)) will find the cond inside thesetq, whereas (f (cond --)) will find the top level cond, i.e., the second one.

*(second . \$)* . same as (lc . \$) followed by another (lc . \$) except that if the first succeeds and second fails, no change is made to the edit chain.

*(third . \$)* . Similar to second.

*(fs pattern1 ... patternn)* . equivalent to *f pattern1* followed by *f pattern2* ... followed by *f pattern n*, so that if *f pattern m* fails, edit chain is left at place pattern m-1 matched.

*(f= expression x)* . Searches for a structure eq to expression.

*(orf pattern1 ... patternn)* . Searches for an expression that is matched by either pattern1 or ... patternn.

*bf pattern* . backwards find. If the current expression is (prog nil (setq x (setq y (list z))) (cond ((setq w --) --)) --) f list followed by bfsetq will leave the current expression as (setq y (list z)), as will f cond followed by bfsetq

*(bf pattern t)*. backwards find. Search always includes current expression, i.e., starts at end of current expression and works backward, then ascends and backs up, etc.

---

**16.3.1.1. Location Specifications** Many editor commands use a method of specifying position called a location specification. The meta-symbol \$ is used to denote a location specification. \$ is a list of commands interpreted as described above. \$ can also be atomic, in which case it is interpreted as (list \$). a location specification is a list of edit commands that are executed in the normal fashion with two exceptions. first, all commands not recognized by the editor are interpreted as though they had been preceded by f. The location specification (cond 2 3) specifies the 3rd element in the first clause of the next cond.

the if command and the ## function provide a way of using in location specifications arbitrary predicates applied to elements in the current expression.

In insert, delete, replace and change, if \$ is nil (empty), the corresponding operation is performed on the current edit chain, i.e. (replace with (car x)) is equivalent to (: (car x)). for added readability, here is also permitted, e.g., (insert (print x) before here) will insert (print x) before the current expression (but not change the edit chain). It is perfectly legal to ascend to insert, replace, or delete. for example (insert (*return*) after ^ prog -1) will go to the top, find the first prog, and insert a (*return*) at its end, and not change the current edit chain.

The a, b, and : commands all make special checks in e1 thru em for expressions of the form (## . coms). In this case, the expression used for inserting or replacing is a copy of the current expression after executing coms, a list of edit commands. (insert (## f cond -1 -1) after3) will make a copy of the last form in the last clause of the next cond, and insert it after the third element of the current expression.

\$ . In descriptions of the editor, the meta-symbol \$ is used to denote a location specification. \$ is a list of commands interpreted as described above. \$ can also be atomic.

#### LOCATION COMMAND SUMMARY

(lc . \$) . Provides a way of explicitly invoking the location operation. (lc cond 2 3) will perform search.

(lcl . \$) . Same as lc except search is confined to current expression. To find a cond containing a *return*, one might use the location specification (cond (lcl *return*)) where the would reverse the effects of the lcl command, and make the final current expression be the cond.

**16.3.2. The Edit Chain** The edit-chain is a list of which the first element is the the one you are now editing ("current expression"), the next element is what would become the current expression if you were to do a 0, etc., until the last element which is the expression that was passed to the editor.

#### EDIT CHAIN COMMAND SUMMARY

mark . Adds the current edit chain to the front of the list marklst.

\_ . Makes the new edit chain be (car marklst).

(\_ pattern) . Ascends the edit chain looking for a link which matches pattern. for example:

\_\_ . Similar to \_ but also erases the mark.

\ . Makes the edit chain be the value of unfind. unfind is set to the current edit chain by each command that makes a "big jump", i.e., a command that usually performs more than a single ascent or descent, namely ^, \_, \_\_, !nx, all commands that involve a search, e.g., f, lc, ::, below, et al and and themselves. if the user types f cond, and then f car, would take him back to the cond. another would take him back to the car, etc.

\p . Restores the edit chain to its state as of the last print operation. If the edit chain has not changed since the last printing, \p restores it to its state as of the printing before that one. If the user types p followed by 3 2 1 p, \p will return to the first p, i.e., would be equivalent to 0 0 0. Another \p would then take him back to the second p.

## 16.4. Printing Commands

---

### PRINTING COMMAND SUMMARY

*p* Prints current expression in abbreviated form. (*p m*) prints *m*th element of current expression in abbreviated form. (*p m n*) prints *m*th element of current expression as though *printlev* were given a depth of *n*. (*p 0 n*) prints current expression as though *printlev* were given a depth of *n*. (*p cond 3*) will work.

? . prints the current expression as though *printlev* were given a depth of 100.

*pp* . pretty-prints the current expression.

*pp\**. is like *pp*, but forces comments to be shown.

---

## 16.5. Structure Modification Commands

All structure modification commands are undoable. See *undo*.

---

### STRUCTURE MODIFICATION COMMAND SUMMARY

# [*editor commands*] (*n*) *n*>1 deletes the corresponding element from the current expression.

(*n e1 ... em*) *n,m*>1 replaces the *n*th element in the current expression with *e1 ... em*.

(-*n e1 ... em*) *n,m*>1 inserts *e1 ... em* before the *n* element in the current expression.

(*n e1 ... em*) (the letter "n" for "next" or "nconc", not a number) *m*>1 attaches *e1 ... em* at the end of the current expression.

(*a e1 ... em*) . inserts *e1 ... em* after the current expression (or after its first element if it is a tail).

(*b e1 ... em*) . inserts *e1 ... em* before the current expression. to insert *foo* before the last element in the current expression, perform -1 and then (*b foo*).

(: *e1 ... em*) . replaces the current expression by *e1 ... em*. If the current expression is a tail then replace its first element.

*delete or (:)* . deletes the current expression, or if the current expression is a tail, deletes its first element.

(*delete . \$*). does a (*lc . \$*) followed by *delete*. current edit chain is not changed.

(*insert e1 ... em before . \$*) . similar to (*lc . \$*) followed by (*b e1 ... em*).

(*insert e1 ... em after . \$*). similar to *insert before* except uses *a* instead of *b*.

(*insert e1 ... em for . \$*). similar to *insert before* except uses *:* for *b*.

(*replace \$ with e1 ... em*) . here *\$* is the segment of the command between *replace* and *with*.

(*change \$ to e1 ... em*) . same as *replace with*.

---

## 16.6. Extraction and Embedding Commands

---

### EXTRACTION AND EMBEDDING COMMAND SUMMARY

*(xtr . \$)* . replaces the original current expression with the expression that is current after performing (*lcl . \$*).

*(mbd x)* . *x* is a list, substitutes the current expression for all instances of the atom \* in *x*, and replaces the current expression with the result of that substitution. (*mbd x*) : *x* atomic, same as (*mbd (x \*)*).

*(extract \$1 from \$2)* . *extract* is an editor command which replaces the current expression with one of its subexpressions (from any depth). (*\$1* is the segment between *extract* and *from*.) example: if the current expression is (*print (cond ((null x) y) (t z))*) then following (*extract y from cond*), the current expression will be (*print y*). (*extract 2 -1 from cond*), (*extract y from 2*), (*extract 2 -1 from 2*) will all produce the same result.

*(embed \$ in . x)* . *embed* replaces the current expression with a new expression which contains it as a subexpression. (*\$* is the segment between *embed* and *in*.) example: (*embed print in setq x*), (*embed 3 2 in return*), (*embed cond 3 1 in (or \* (null x))*).

---

## 16.7. Move and Copy Commands

---

### MOVE AND COPY COMMAND SUMMARY

*(move \$1 to com . \$2)* . (*\$1* is the segment between *move* and *to*.) where *com* is before, after, or the name of a list command, e.g., *:*, *n*, etc. If *\$2* is nil, or (*here*), the current position specifies where the operation is to take place. If *\$1* is nil, the move command allows the user to specify some place the current expression is to be moved to. if the current expression is (*a b d c*), (*move 2 to after 4*) will make the new current expression be (*a c d b*).

*(mv com . \$)* . is the same as (*move here to com . \$*).

*(copy \$1 to com . \$2)* is like *move* except that the source expression is not deleted.

*(cp com . \$)* . is like *mv* except that the source expression is not deleted.

---

## 16.8. Parentheses Moving Commands

The commands presented in this section permit modification of the list structure itself, as opposed to modifying components thereof. their effect can be described as inserting or removing a single left or right parenthesis, or pair of left and right parentheses.

---

### PARENTHESES MOVING COMMAND SUMMARY

*(bi n m)* . both in. inserts parentheses before the *n*th element and after the *m*th element in the current expression. example: if the current expression is (*a b (c d e) f g*), then (*bi 2 4*) will modify it to be (*a (b (c d e) f) g*). (*bi n*) : same as (*bi n n*). example: if the current expression is (*a b (c d e) f g*), then (*bi -2*) will modify it to be (*a b (c d e) (f) g*).

*(bo n)* . both out. removes both parentheses from the *n*th element. example: if the current expression is (*a b (c d e) f g*), then (*bo d*) will modify it to be (*a b c d e f g*).

*(li n)* . left in. inserts a left parenthesis before the *n*th element (and a matching right parenthesis at the end of the current expression).

example: if the current expression is (a b (c d e) f g), then (li 2) will modify it to be (a (b (c d e) f g)).

(lo n) . left out. removes a left parenthesis from the nth element. all elements following the nth element are deleted. example: if the current expression is (a b (c d e) f g), then (lo 3) will modify it to be (a b c d e).

(ri n m) . right in. move the right parenthesis at the end of the nth element in to after the mth element. inserts a right parenthesis after the mth element of the nth element. The rest of the nth element is brought up to the level of the current expression. example: if the current expression is (a (b c d e) f g), (ri 2 2) will modify it to be (a (b c) d e f g).

(ro n) . right out. move the right parenthesis at the end of the nth element out to the end of the current expression. removes the right parenthesis from the nth element, moving it to the end of the current expression. all elements following the nth element are moved inside of the nth element. example: if the current expression is (a b (c d e) f g), (ro 3) will modify it to be (a b (c d e f g)).

(r x y) replaces all instances of x by y in the current expression, e.g., (r caadr cadar). x can be the s-expression (or atom) to be substituted for, or can be a pattern which specifies that s-expression (or atom).

(sw n m) switches the nth and mth elements of the current expression. for example, if the current expression is (list (cons (car x) (car y)) (cons (cdr x) (cdr y))), (sw 2 3) will modify it to be (list (cons (cdr x) (cdr y)) (cons (car x) (car y))). (sw car cdr) would produce the same result.

### 16.8.1. Using to and thru

to, thru, extract, embed, delete, replace, and move can be made to operate on several contiguous elements, i.e., a segment of a list, by using the to or thru command in their respective location specifications. thru and to are intended to be used in conjunction with extract, embed, delete, replace, and move. to and thru can also be used directly with xtr (which takes after a location specification), as in (xtr (2 thru 4)) (from the current expression).

#### TO AND THRU COMMAND SUMMARY

(\$1 to \$2) . same as thru except last element not included.

(\$1 to). same as (\$1 thru -1)

(\$1 thru \$2) . If the current expression is (a (b (c d) (e) (f g h) i) j k), following (c thru g), the current expression will be ((c d) (e) (f g h)). If both \$1 and \$2 are numbers, and \$2 is greater than \$1, then \$2 counts from the beginning of the current expression, the same as \$1. in other words, if the current expression is (a b c d e f g), (3 thru 4) means (c thru d), not (c thru f). in this case, the corresponding bi command is (bi 1 \$2-\$1+1).

(\$1 thru). same as (\$1 thru -1).

**16.9. Undoing Commands** each command that causes structure modification automatically adds an entry to the front of undolst containing the information required to restore all pointers that were changed by the command. The undo command undoes the last, i.e., most recent such command.

---

*UNDO COMMAND SUMMARY*

*undo* . the undo command undoes most recent, structure modification command that has not yet been undone, and prints the name of that command, e.g., mbd undone. The edit chain is then exactly what it was before the 'undone' command had been performed.

*!undo* . undoes all modifications performed during this editing session, i.e., this call to the editor.

*unlock* . removes an undo-block. If executed at a non-blocked state, i.e., if undo or !undo could operate, types not blocked.

*test* . adds an undo-block at the front of undolst. note that test together with !undo provide a 'tentative' mode for editing, i.e., the user can perform a number of changes, and then undo all of them with a single !undo command.

*undolst [value]* . each editor command that causes structure modification automatically adds an entry to the front of undolst containing the information required to restore all pointers that were changed by the command.

*??* prints the entries on undolst. The entries are listed most recent entry first.

---

## 16.10. Commands that Evaluate

---

*EVALUATION COMMAND SUMMARY*

*e* . only when typed in, (i.e., (insert d before e) will treat e as a pattern) causes the editor to call the lisp interpreter giving it the next input as argument.

*(e x)* evaluates x, and prints the result. *(e x t)* same as *(e x)* but does not print.

*(i c x1 ... xn)* same as *(c y1 ... yn)* where  $y_i = (\text{eval } x_i)$ . example: *(i 3 (cdr foo))* will replace the 3rd element of the current expression with the cdr of the value of foo. *(i n foo (car fie))* will attach the value of foo and car of the value of fie to the end of the current expression. *(i f= foo t)* will search for an expression eq to the value of foo. If c is not an atom, it is evaluated as well.

*(coms x1 ... xn)* . each  $x_i$  is evaluated and its value executed as a command. The *i* command is not very convenient for computing an entire edit command for execution, since it computes the command name and its arguments separately. also, the *i* command cannot be used to compute an atomic command. The *coms* and *comsq* commands provide more general ways of computing commands. *(coms (cond (x (list 1 x))))* will replace the first element of the current expression with the value of x if non-nil, otherwise do nothing. (nil as a command is a nop.)

*(comsq com1 ... comn)* . executes com1 ... comn. *comsq* is mainly useful in conjunction with the *coms* command. for example, suppose the user wishes to compute an entire list of commands for evaluation, as opposed to computing each command one at a time as does the *coms* command. he would then write *(coms (cons (quote comsq) x))* where x computed the list of commands, e.g., *(coms (cons (quote comsq) (get foo (quote commands))))*

---

## 16.11. Commands that Test

---

*TESTING COMMAND SUMMARY*

*(if x)* generates an error unless the value of *(eval x)* is non-nil, i.e., if *(eval x)* causes an error or *(eval x)=nil*, it will cause an error. *(if x coms1 coms2)* if *(eval x)* is non-nil, execute *coms1*; if *(eval x)* causes an error or is equal to nil, execute *coms2*. *(if x coms1)* if *(eval x)* is non-nil, execute *coms1*; otherwise generate an error.

*(lp . coms)* repeatedly executes *coms*, a list of commands, until an error occurs. *(lp f print (n t))* will attach a *t* at the end of every print expression. *(lp f print (if (## 3) nil ((n t))))* will attach a *t* at the end of each print expression which does not already have a second argument. (i.e. the form *(## 3)* will cause an error if the edit command 3 causes an error, thereby selecting *((n t))* as the list of commands to be executed. The *if* could also be written as *(if (caddr (##)) nil ((n t)))*).

*(lpq . coms)* same as *lp* but does not print *n* occurrences.

*(orr coms1 ... comsn)* . *orr* begins by executing *coms1*, a list of commands. If no error occurs, *orr* is finished. otherwise, *orr* restores the edit chain to its original value, and continues by executing *coms2*, etc. If none of the command lists execute without errors, i.e., the *orr* "drops off the end", *orr* generates an error. otherwise, the edit chain is left as of the completion of the first command list which executes without error.

---

**16.12. Editor Macros**

Many of the more sophisticated branching commands in the editor, such as *orr*, *if*, etc., are most often used in conjunction with edit macros. The macro feature permits the user to define new commands and thereby expand the editor's repertoire. (however, built in commands always take precedence over macros, i.e., the editor's repertoire can be expanded, but not modified.) macros are defined by using the *m* command.

*(m c . coms)* for *c* an atom, *m* defines *c* as an atomic command. (if a macro is redefined, its new definition replaces its old.) executing *c* is then the same as executing the list of commands *coms*. macros can also define list commands, i.e., commands that take arguments. *(m (c) (arg[1] ... arg[n]) . coms)* *c* an atom. *m* defines *c* as a list command. executing *(c e1 ... en)* is then performed by substituting *e1* for *arg[1]*, ... *en* for *arg[n]* throughout *coms*, and then executing *coms*. a list command can be defined via a macro so as to take a fixed or indefinite number of 'arguments'. The form given above specified a macro with a fixed number of arguments, as indicated by its argument list. if the of arguments. *(m (c) args . coms)* *c*, *args* both atoms, defines *c* as a list command. executing *(c e1 ... en)* is performed by substituting *(e1 ... en)*, i.e., *cdr* of the command, for *args* throughout *coms*, and then executing *coms*.

*(m bp bk up p)* will define *bp* as an atomic command which does three things, a *bk*, an *up*, and a *p*. note that macros can use commands defined by macros as well as built in commands in their definitions. for example, suppose *z* is defined by *(m z -1 (if (null (##)) nil (p)))*, i.e. *z* does a *-1*, and then if the current expression is not nil, a *p*. now we can define *zz* by *(m zz -1 z)*, and *zzz* by *(m zzz -1 -1 z)* or *(m zzz -1 zz)*. we could define a more general *bp* by *(m (bp) (n) (bk n) up p)*. *(bp 3)* would perform *(bk 3)*, followed by an *up*, followed by a *p*. The command second can be defined as a macro by *(m (2nd) x (orr ((lc . x) (lc . x))))*.

Note that for all editor commands, 'built in' commands as well as commands defined by macros, atomic definitions and list definitions are completely independent. in other words, the existence of an atomic definition for *c* in no way affects the treatment of *c* when it appears as *car* of a list command, and the existence of a list definition for *c* in no way affects the treatment of *c* when it appears as an atom. in particular, *c* can be used as the name of either an atomic command, or a list command, or both. in the latter case, two entirely different definitions can be used. note also that once *c* is defined as an atomic command via a macro definition, it will not be searched for when used in a location specification, unless *c* is preceded by an *f*. *(insert -- before bp)* would not search

for bp, but instead perform a bk, an up, and a p, and then do the insertion. The corresponding also holds true for list commands.

*(bind . coms)* bind is an edit command which is useful mainly in macros. it binds three dummy variables #1, #2, #3, (initialized to nil), and then executes the edit commands coms. note that these bindings are only in effect while the commands are being executed, and that bind can be used recursively; it will rebind #1, #2, and #3 each time it is invoked.

*usermacros [value]*. this variable contains the users editing macros . if you want to save your macros then you should save usermacros. you should probably also save editcomsl.

*editcomsl [value]*. editcomsl is the list of "list commands" recognized by the editor. (these are the ones of the form (command arg1 arg2 ...).)

### 16.13. Miscellaneous Editor Commands

---

#### MISCELLANEOUS EDITOR COMMAND SUMMARY

*ok* . Exits from the editor.

*nil* . Unless preceded by f or bf, is always a null operation.

*tty:* . Calls the editor recursively. The user can then type in commands, and have them executed. The *tty:* command is completed when the user exits from the lower editor (with *ok* or *stop*). the *tty:* command is extremely useful. it enables the user to set up a complex operation, and perform interactive attention-changing commands part way through it. for example the command (move 3 to after cond 3 p *tty:*) allows the user to interact, in effect, within the move command. he can verify for himself that the correct location has been found, or complete the specification "by hand". in effect, *tty:* says "I'll tell you what you should do when you get there."

*stop* . exits from the editor with an error. mainly for use in conjunction with *tty:* commands that the user wants to abort. since all of the commands in the editor are *errset* protected, the user must exit from the editor via a command. *stop* provides a way of distinguishing between a successful and unsuccessful (from the user's standpoint) editing session.

*tl* . *tl* calls (top-level). to return to the editor just use the *return* top-level command.

*repack* . permits the 'editing' of an atom or string.

*(repack \$)* does (lc . \$) followed by *repack*, e.g. (*repack this@*).

*(makefn form args n m)* . makes (car form) an expr with the nth through mth elements of the current expression with each occurrence of an element of (cdr form) replaced by the corresponding element of args. The nth through mth elements are replaced by form.

*(makefn form args n)*. same as (makefn form args n).

*(s var . \$)* . sets var (using *setq*) to the current expression after performing (lc . \$). (*s foo*) will set foo to the current expression, (*s foo -1 1*) will set foo to the first element in the last element of the current expression.

---

### 16.14. Editor Functions

**(editf s\_x1 ...)**

SIDE EFFECT: edits a function. s\_x1 is the name of the function, any additional arguments are an optional list of commands.

RETURNS: s\_x1.

NOTE: if s\_x1 is not an editable function, editf generates an fn not editable error.

**(edite l\_expr l\_coms s\_atm)**

edits an expression. its value is the last element of (editl (list l\_expr) l\_coms s\_atm nil nil).

**(editracefn s\_com)**

is available to help the user debug complex edit macros, or subroutine calls to the editor. editracefn is to be defined by the user. whenever the value of editracefn is non-nil, the editor calls the function editracefn before executing each command (at any level), giving it that command as its argument. editracefn is initially equal to nil, and undefined.

**(editv s\_var [ g\_com1 ... ])**

SIDE EFFECT: similar to editf, for editing values. editv sets the variable to the value returned.

RETURNS: the name of the variable whose value was edited.

**(editp s\_x)**

SIDE EFFECT: similar to editf for editing property lists. used if x is nil.

RETURNS: the atom whose property list was edited.

**(editl coms atm marklst mess)**

SIDE EFFECT: editl is the editor. its first argument is the edit chain, and its value is an edit chain, namely the value of l at the time editl is exited. (l is a special variable, and so can be examined or set by edit commands. ^ is equivalent to (e (setq l(last l)) t).) coms is an optional list of commands. for interactive editing, coms is nil. in this case, editl types edit and then waits for input from the teletype. (if mess is not nil editl types it instead of edit. for example, the tty: command is essentially (setq l (editl l nil nil nil (quote tty:))) exit occurs only via an ok, stop, or save command. If coms is not nil, no message is typed, and each member of coms is treated as a command and executed. If an error occurs in the execution of one of the commands, no error message is printed, the rest of the commands are ignored, and editl exits with an error, i.e., the effect is the same as though a stop command had been executed. If all commands execute successfully, editl returns the current value of l. marklst is the list of marks. on calls from editf, atm is the name of the function being edited; on calls from editv, the name of the variable, and calls from editp, the atom of which some property of its property list is being edited. The property list of atm is used by the save command for saving the state of the edit. save will not save anything if atm=nil i.e., when editing arbitrary expressions via edite or editl directly.

**(editfns s\_x [ g\_com1 ... ])**

fsubr function, used to perform the same editing operations on several functions. editfns maps down the list of functions, prints the name of each function, and calls the editor (via editf) on that function.

EXAMPLE: editfns foofns (r fie fum) will change every fie to fum in each of the functions on foofns.

NOTE: the call to the editor is errset protected, so that if the editing of one function causes an error, editfns will proceed to the next function. in the above example, if one of the functions did not contain a fie, the r command would cause an error, but editing would continue with the next function. The value of editfns is nil.

**(edit4e pat y)**

SIDE EFFECT: is the pattern match routine.

RETURNS: t if pat matches y. see edit-match for definition of 'match'.

NOTE: before each search operation in the editor begins, the entire pattern is scanned for atoms or strings that end in at-signs. These are replaced by patterns of the form (cons (quote /@) (explodec atom)). from the standpoint of edit4e, pattern type 5, atoms or strings ending in at-signs, is really "if car[pat] is the atom @ (at-sign), pat will match with any literal atom or string whose initial character codes (up to the @) are the same as those in cdr[pat]." if the user wishes to call edit4e directly, he must therefore convert any patterns which contain atoms or strings ending in at-signs to the form recognized by edit4e. this can be done via the function editfpat.

**(editfpat pat flg)**

makes a copy of pat with all patterns of type 5 (see edit-match) converted to the form expected by edit4e. flg should be passed as nil (flg=t is for internal use by the editor).

**(editfindp x pat flg)**

NOTE: Allows a program to use the edit find command as a pure predicate from outside the editor. x is an expression, pat a pattern. The value of editfindp is t if the command f pat would succeed, nil otherwise. editfindp calls editfpat to convert pat to the form expected by edit4e, unless flg=t. if the program is applying editfindp to several different expressions using the same pattern, it will be more efficient to call editfpat once, and then call editfindp with the converted pattern and flg=t.

**(## g\_com1 ...)**

RETURNS: what the current expression would be after executing the edit commands com1 ... starting from the present edit chain. generates an error if any of comi cause errors. The current edit chain is never changed. example: (i r (quote x) (## (cons .z))) replaces all x's in the current expression by the first cons containing a z.

## CHAPTER 17

### Hash Tables

#### 17.1. Overview

A hash table is an object that can efficiently map a given object to another. Each hash table is a collection of entries, each of which associates a unique *key* with a *value*. There are elemental functions to add, delete, and find entries based on a particular key. Finding a value in a hash table is relatively fast compared to looking up values in, for example, an assoc list or property list.

Adding a key to a hash table modifies the hash table, and so it is a destructive operation.

There are two different kinds of hash tables: those that use the function *equal* for the comparing of keys, and those that use *eq*, the default. If a key is "eq" to another object, then a match is assumed. Likewise with "equal".

#### 17.2. Functions

**(makeht** *x\_size* [*s\_test*])

RETURNS: A hash table of *x\_size* hash buckets. If present, *s\_test* is used as the test to compare keys in the hash table, the default being **eq**. *Equal* might be used to create a hash table where the keys are to be lists (or any lisp object).

NOTE: At this time, hash tables are implemented on top of vectors.

**(hash-table-p** *H\_arg*)

RETURNS: **t** if *H\_arg* is a hash table.

NOTE: Since hash tables are really vectors, the lisp type of a hash table is a vector, so that given a vector, this function will return **t**.

**(gethash** *g\_key* *H\_htable* [*g\_default*])

RETURNS: the value associated the key *g\_key* in hash table *H\_htable*. If there is not an entry given by the key and *g\_default* is specified, then *g\_default* is returned, otherwise, a symbol that is unbound is returned. This is so that **nil** can be associated with a key.

NOTE: *setf* may be used to set the value associated with a key.

**(remhash 'g\_key 'H\_htable)**

RETURNS: t if there was an entry for g\_key in the hash table H\_htable, nil otherwise. In the case of a match, the entry and associated object are removed from the hash table.

**(maphash 'u\_func 'H\_htable)**

RETURNS: nil.

NOTE: The function u\_func is applied to every element in the hash table H\_htable. The function is called with two arguments: the key and value of an element. The mapped function should not add or delete object from the table because the results would be unpredictable.

**(clrhash 'H\_htable)**

RETURNS: the hash table cleared of all entries.

**(hash-table-count 'H\_htable)**

RETURNS: the number of entries in H\_htable. Given a new hash table with no entries, this function returns zero.

---

```

; make a vanilla hash table using "eq" to compare items...
[]> (setq black-box (makeht 20))
